Abstract: A series of meso-amino(methyl)azanoradamantane benzamides have been prepared and evaluated for 5-HT₄ agonism activity in the rat tunica muscularis mucosae (TMM) assay. Compound **8i** is the most potent 5-HT₄ agonist in the series, with an EC₅₀ of 217 nM.

The serotonin 5-HT₄ receptor has been identified in a variety of tissues and mediates an impressive array of functional responses.¹ The 5-HT₄ receptor was first described by Dumuis and Bockaert² in mouse embryo colliculi neurons and by Craig and Clarke³ in guinea-pig ileum. Furthermore, agonist activity at this receptor has been correlated with gastrointestinal prokinetic activity of prokinetic benzamides, including metoclopramide, zacopride, cisapride and renzapride.⁴ Novel and potent 5-HT₄ agonists have potential in treating gastrointestinal motility disorders including reflux esophagitis, non-ulcer dyspepsia (NUD) and the irritable bowel syndrome (IBS). Continuing efforts in this area have led to a number of potent agonists for the 5-HT₄ receptor.⁵

In earlier communications⁶ we disclosed a series of azaadamantane and azanoradamantane benzamides, including the potent 5-HT₄ agonist/5-HT₃ antagonist, SC-52491, which has an EC₅₀ of 51 nM in the tunica muscularis mucosae assay and a K_i of 1.2 nM at the 5-HT₃ receptor. SC-52491 is also highly selective versus other monoamine receptors, with IC₅₀s >10,000 nM for serotonin 5-HT₁ and 5-HT₂ receptors; dopamine D₁ and D₂ receptors; alpha-1, alpha-2 and beta adrenergic receptors; as well as muscarinic and substance P receptors. We previously described the synthesis of the anti-4(R)-amino derivative of azacycle **I**^{6a,7} for the preparation of SC-52491, which contains four contiguous asymmetric centers. We subsequently focussed our attention on a series of azanoradamantanes as serotonergics in order to capitalize on their conformationally rigid structure to produce analogs with high potency and selectivity. We were specifically attracted to achiral substituted azanoradamantane scaffolds which exhibit a plane of symmetry. Benzamides produced from these scaffolds would obviate the need for either asymmetric synthesis or resolution.

Figure I

The azanoradamantane skeleton possesses two nonequivalent bridgehead positions. Incorporation of a nitrogen atom at either of these two bridgehead positions leads to two isomeric azanoradamantanes, **I** and **II** (Figure I). Both **I** and **II** belong to the C_s symmetry group and as such are *meso*-structures. This symmetry is retained if substitution is made at the 5-position on azanoradamantane **I** or at the 8-position of azanoradamantane **II**.

Compounds containing the meso-azanoradamantane skeleton of type **I** have not been reported in the literature. Azanoradamantanes of type **II** had previously been synthesized by Speckamp,⁸ and this skeleton is

present in natural products, including (+)-aristofrutosane.⁹ Herein we describe the 5-HT₄ and 5-HT₃ properties of novel benzamide derivatives of amino(alkyl) derivatives of both isomeric meso-azanoradamantanes **I** and **II**. The requisite amino(alkyl)azanoradamantanes are shown in Figure II.

Figure II

The aminomethylazanoradamantane **Ia** was prepared as shown in Scheme I. Reduction of **1**,⁷ prepared by our tandem atom-transfer radical cyclization/ionic cyclization methodology, was reduced with lithium borohydride to give the diol **2**. Treatment with an excess of tosyl chloride gave the bis-tosylate which was deprotected with trifluoroacetic acid and cyclized with cesium chloride to give the azanoradamantane tosylate **3** in excellent yield. Displacement of the neopentyl tosylate with azide followed by reduction with lithium aluminum hydride gave aminomethyl azanoradamantane **Ia**.

The homologated derivative **Ib** was prepared via treatment of the azanoradamantane tosylate **3** with potassium cyanide followed by reduction with lithium aluminum hydride to give the aminoethyl azanoradamantane **Ib** (Scheme II).

Scheme I

Scheme II

The isomeric *endo*- and *exo*-aminoazanoradamantanes of type **II** were prepared from azanoradamantanone **4**⁸ by reduction of the O-benzyl oxime to give *endo*-**IIa**¹⁰ and *exo*-**IIa**¹⁰ as a 1:1 mixture (Scheme III). Alternatively, reductive homologation of azanoradamantanone **4** with tosylmethyl isocyanide (TosMIC),¹¹ as we had done previously on 1-azaadamantan-4-one,¹² gave the isomeric *endo*- and *exo*-nitriles **5** which were separable by flash chromatography on silica gel. Subsequent reduction with lithium aluminum

hydride on each nitrile isomer separately gave the corresponding aminoazaadamantanes **endo-IIb** and **exo-IIb**, respectively.

With the requisite amino(methyl)azanoradamantanes in hand, it remained to couple these amines with the appropriate benzoic acid derivative as shown in Scheme IV. 4-Acetamido-5-chloro-2-methoxybenzoic acid **6** was treated with 1,1'-carbonyldiimidazole (CDI) followed by the appropriate amino(alkyl)azanoradamantane (Z-NH₂) followed by deprotection with methanolic potassium hydroxide (except for **8f-h**, which were tested as the acetamides). More conveniently, 4-amino-5-chloro-2-methoxybenzoic acid **7** can be treated directly with CDI followed by the appropriate amine to give the benzamide **8** (R=H).

Scheme III

Scheme IV

The 5-HT₄ agonist activities are summarized in Table I, and SC-52491 (**8a**) is included as a reference standard. The endo derivative **8b** showed modest 5-HT₄ agonist activity in the rat tunica muscularis mucosae assay¹³ with an EC₅₀ of 712 nM, but the exo isomer **8b** was twice as potent with an EC₅₀ of 382 nM. We observed that epimeric homologation increases the potency in the azaadamantane series.¹² However, the 5-HT₄ agonist potency was comparable for **8d** and **8c**.

The corresponding acetamide derivatives **8f**, **8g**, and **8h** (1:1 epimeric mixture) were essentially devoid of 5-HT₄ activity. The acetamide **8f** did exhibit rather weak 5-HT₄ agonism (3.3 μM) and the unparallel slope observed for this compound suggested that this analog may have been acting as a partial agonist. It is not known if these compounds have 5-HT₄ antagonist activity.

The derivative **8i** was the most potent meso-azanoradamantane examined in this study, exhibiting an EC₅₀ of 217 nM. The homolog **8j** was almost an order of magnitude less potent.

Azanoradamantane benzamide **8i** was selected for further study on the basis of its more potent 5-HT₄ agonist activity. The compound is also a potent 5-HT₃ antagonist, having a K_i of 5.0 (0.5) nM in the 5-HT₃ binding assay of Kilpatrick,¹⁴ and exhibiting 70% inhibition of the serotonin 5-HT₃-mediated bradycardia in the Bezold-Jarisch reflex model¹⁵ in mice at 1 mpk after I.P. administration. The compound was selective with respect to binding at the dopamine D₂ receptor (IC₅₀ >10,000 nM).

In summary, we have synthesized two new series of amino(alkyl)azanoradamantane benzamides which exhibit 5-HT₄ agonism as well as affinity for the 5-HT₃ receptor. SC-55387 was the most potent 5-HT₄ agonist in the present study with an IC₅₀ of 217 nM in the rat TMM assay and a K_i of 5.0 (0.5) nM at the 5-HT₃ receptor. These meso-compounds have the distinct advantage of being achiral, although the compounds of the present series were not as potent as SC-52491 in 5-HT₄ agonist activity or 5-HT₃ antagonist activity.
