A series of pyrrolizidine esters, amides and ureas were prepared and tested for 5-HT$_4$ and 5-HT$_3$ receptor binding, 5-HT$_4$ receptor agonism in the rat tunica muscularis mucosae (TMM) assay, and for 5-HT$_3$ receptor-mediated functional antagonism in the Bezold-Jarisch reflex assay. Several pyrrolizidine derivatives were identified with high affinity for the 5-HT$_4$ receptor including benzamide 12a (SC-53116), a potent and selective 5-HT$_4$ partial agonist that exhibits efficacy in promoting antral contractions and activity in promoting gastric emptying in canine models. Also discovered were 5-HT$_4$ receptor antagonists, including imidazopyridine amide 12h (SC-53606), which is a potent and selective 5-HT$_4$ receptor antagonist with a pA$_2$ value of 8.13 in the rat TMM assay. N-Methyl indole ester 13d was identified as a potent 5-HT$_4$ antagonist with a pA$_2$ value of 8.93. High selectivity was observed for these pyrrolizidine derivatives versus other monoamine receptors including 5-HT$_1$, 5-HT$_2$, D$_1$, D$_2$, $\alpha_1$, $\alpha_2$ and $\beta$ receptors.

**Introduction**

Serotonin (5-hydroxytryptamine, 5-HT) functions as both a hormone and a neurotransmitter, controlling a host of central and peripheral effects in mammalian systems, and is noteworthy in its diversity of receptors and subtypes.$^1$ Given the diversity and ubiquitous nature of serotonin receptors, it is imperative to prepare potent and selective 5-HT ligands to enable pharmacological studies of the various receptor subtypes and to serve as drugs to treat diseases that have an etiology in serotonin receptor imbalance.

The 5-HT$_4$ receptor was discovered by Baxter, Craig and Clarke$^2$ and by Dumuis and Bockaert$^3$ in the gut and brain, respectively, and is expressed in a wide variety of tissues including brain, heart, bladder, gut and kidney$^4,5$ Initial demonstration that the
gastrointestinal prokinetic benzamides cisapride (compounds 1) and renzapride (compound 2) enhance contractile activity at neuronal 5-HT₄ receptors in the guinea pig ileum was made by Craig and Clarke. It was later demonstrated by Dumuis and Bockaert that 5-HT₄ receptors mediate the relaxation of smooth muscle of the inner muscularis mucosae of rat esophagus and also the cholinergic stimulation of the ascending colon of the guinea pig. New tools including fluorescent antagonists have recently been developed for the study of 5-HT₄ receptors, and an excellent review of the 5-HT₄ receptor and key ligands was recently published.

Selective ligands for the 5-HT₄ receptor show promise in the treatment of a wide variety of diseases including the irritable bowel syndrome (IBS) and other gastrointestinal motility disorders, urinary incontinence, atrial arrhythmia and cognitive disorders. Gastrointestinal motility disorders are a collection of syndromes which are characterized by a hypofunctional bowel, abnormal motility patterns and transit, and painful gut wall distension. The mechanisms thought to be common to many of these motility disorders is the malfunction of enteric nervous system control of peristalsis at the level of the myenteric plexus. Compound 1 had been marketed for motility disorders but was withdrawn due to QT prolongation. The 5-HT₄ partial agonist tegaserod (compound 3, SDZ HTF 919) was approved in 2002 for the treatment of constipation-predominant irritable bowel syndrome (IBS). Tegaserod shows a clear effect on the total colonic transit time in healthy subjects, and a significant improvement in patients with constipation-predominant IBS in a phase III trial. Compound 4, Prucalopride, accelerates colonic transit in healthy subjects but without modification of either gastric emptying or small bowel transit. In patients with severe constipation, the benzamide prucalopride elicited a dose-dependent effect on acceleration of the overall transit time.
We have pursued the exploration of various conformationally-constrained bicyclic and tricyclic amines as ligands for the serotonin 5-HT$_4$ receptor to treat gastrointestinal motility disorders. Our focus has been on receptor selectivity to avoid potential side effects, and we were particularly cognizant of avoiding the dopamine D$_2$ receptor, as D$_2$ antagonism is responsible for extrapyramidal side effects and hyperprolactinaemia observed with the marketed benzamide metoclopramide.\textsuperscript{25} We were also vigilant of other monoamine receptors, including the 5-HT$_2$ receptor, which is potently inhibited by compound 1.\textsuperscript{26} We were attracted to the pyrrolizidine azabicyclo[3.3.0]octane ring system and reasoned that this fairly rigid bicyclic amine could provide a fruitful scaffold for preparing potent and selective serotonin 5-HT$_4$ agonists. A similar approach was used by King in the discovery of renzapride (2), which was designed to mimic the higher energy conformers of azabicyclic quinolizidine benzamides of their earlier studies,\textsuperscript{27} and in particular was designed to lock in the cis form of the ring junction of the azabicycle and reduce the steric bulk extending outward around the basic nitrogen. The Beecham group then also employed a pyrrolizidine scaffold.\textsuperscript{28, 29} More recently, the 5-HT$_4$ receptor agonist meso-pyrrolizidine 5 (SK-951) has been described which is a potent gastrointestinal prokinetic agent in rats and dogs.\textsuperscript{30, 31} Our own successful approach employing the pyrrolizidine moiety led to the potent 5-HT$_4$ receptor partial agonist 12a\textsuperscript{32} by attaching the pyrrolizidine to the traditional aromatic moiety of prokinetic benzamides 1 and 2. In addition, we explored the attachment of other aromatic amides to the pyrrolizidine bicyclic amine, seeking to mimic the intramolecular H-bond of the 2-methoxybenzamides. This approach led to the potent 5-HT$_4$ receptor antagonist 12h.\textsuperscript{33} We also explored both amides and esters of the pyrrolizidine amine moiety with indole and indazole aromatic moieties, inspired by the potent 5-HT$_3$ receptor antagonists
tropisetron\textsuperscript{34} and granisetron,\textsuperscript{34, 35} particularly considering that tropisetron was shown to be the first surmountable antagonist of 5-HT\textsubscript{4} receptors\textsuperscript{3} and Buchheit demonstrated that the ester derivative of metoclopramide, SDZ 205-557, is a potent antagonist of 5-HT\textsubscript{4} receptors.\textsuperscript{36}

We were aware of the toxicity of the pyrrolizidine alkaloid natural products\textsuperscript{37} and considered the fact that toxicity among pyrrolizidine alkaloids varies dramatically with differences in chemical structure. Certain pyrrolizidine natural products can form highly reactive pyrrole intermediates upon metabolism by CYP3A4 which are responsible for their nascent toxicity. A ring nucleus containing a double bond at the 1,2-position is considered to be essential for toxic effects of the alkaloid, along with additional hydroxyl groups around the nucleus. Based on this premise of structure-specificity we decided to explore the pyrrolizidine nucleus for incorporation into novel 5-HT\textsubscript{4} receptor agonists and antagonists. This paper details our work employing the pyrrolizidine scaffold resulting in the potent 5-HT\textsubscript{4} receptor agonist 12\textsubscript{a}, as well as 5-HT\textsubscript{4} receptor antagonist 12\textsubscript{h}, and other potent 5-HT\textsubscript{4} antagonists.

**Chemistry**

The (S,S)-carbinol (-)-trachelanthamidine 9 was prepared by a diastereoselective alkylation of the chiral tin enolate of 3-(4-chlorobutyryl)-4-(S)-isopropyl-1,3-thiazolidine-2-thione 7 with 5-acetoxy-2-pyrrolidinone as elegantly described by Yoshimitsu Nagao\textsuperscript{38} and summarized in Scheme 1. We analyzed the Mosher ester of 9 by $^{19}$F NMR to confirm the enantiomeric purity which showed the material to be $\geq 99.1\%$ e.e.

Aminomethylpyrrolizidine 11 was prepared by Mistunobu reaction of 9 with phthalimide in the presence of triphenylphosphine and diethylazodicarboxylate to afford phthalimide
derivative 10, and the phthalimide moiety was removed with hydrazine to afford 11 (Scheme 2). Coupling of the amine with an aryl carboxylic acid was then typically accomplished with 1,1’-carbonyl diimidazole (CDI) to give the requisite pyrrolizidine amides 12. Esters of 9 were prepared by treating the imidazolide derived from the appropriate aryl carboxylic acid and CDI with the sodium salt of alcohol 9 to afford esters 13 (Scheme 3). The enantiomer of aminomethylpyrrolizidine 11 and its derivatives (in particular, benzamide ent-12a, the enantiomer of 12a, were prepared from the (R)-enantiomer of thiazolidine 7.

Benzimidazolone 15a and oxindole urea 15b were prepared by treatment of the sodium salt of the corresponding benzimidazolone 14a or oxindole 14b with phosgene followed by the aminomethylpyrrolizidine 11 (Scheme 4). Imidazol[1,2-a]pyridine-8-carboxylic acid 17 was prepared by reacting 2-aminonicotinic acid 16 with chloroacetaldehyde, and 6-chloroimidazo[1,2-a]pyridine-8-carboxylic acid 19 was prepared from methyl 2-amino-5-chloronicotinate 18 with chloroacetaldehyde followed by saponification (Scheme 5). Similarly, 6-chloroimidazo[1,2-a]pyridine-3-methyl-8-carboxylic acid 21 was prepared by alkylation of 2-aminonicotinic acid 16, and regioselective chlorination with t-butyl hypochlorite to afford 20, followed by conversion to the imidazopyridine with 2-bromopropionaldehyde and hydrolysis of the ester to afford carboxylic acid 21 (Scheme 6). The pyrrolizidine esters and amides of these imidazopyridines were prepared by the general methods described in Schemes 2 and 3.
Results and Discussion

Initial testing of pyrrolizidine 5-HT₄ receptor ligands was accomplished using the rat esophageal tunica muscularis mucosal (TMM) tissue²⁻³⁹ as this model allows for determination of full cumulative dose response curves to agonists. Serotonin 5-HT₄ receptor antagonists were also evaluated using the TMM model. Binding to serotonin 5-HT₄ receptors in guinea pig striatum was measured utilizing [³H]-GR113,808 as the ligand. Binding to serotonin 5-HT₃ receptors in rat cortical tissue was measured using [³H]-GR656630. Functional 5-HT₃ antagonism was measured utilizing the von Bezold-Jarisch reflex model.⁴⁰

Pyrrolizidine 5-HT₄ agonists are summarized in Table 1. In the rat TMM assay, the chiral pyrrolizidine benzamide 12a and its distomer ent-12a had EC₅₀ values of 16.5 ± 3.8 nM and 323 ± 46 nM, respectively. A plot of the TMM activity of 12a and ent-12a relative to serotonin is shown in Figure 2 demonstrating that the pyrrolizidine benzamide 12a has comparable potency to serotonin (16.5 nM vs. 9.0 nM for 5-HT) and has 80% of the efficacy of serotonin in this preparation. The distomer ent-12a is 36 times less potent than serotonin. The potency of 12a relative to its enantiomer is reflected in 5-HT₄ receptor binding. Pyrrolizidine 12a has a Kᵢ value of 5.2 nM, while ent-12a inhibits ligand binding by only 18% at 500 nM (Table 1). Benzamide 12a is approximately 30X more potent in binding to the 5-HT₄ receptor relative to its 5-HT₃ binding (Kᵢ = 152 nM). In contrast to the 30X difference in 5-HT₄ binding, 12a is only half as potent as ent-12a in 5-HT₃ binding. We previously reported a similar trend with compound 6 and its enantiomer, where the 5-HT₄ receptor showed a greater discernment of the antipodes than the 5-HT₃ receptor, although in that case the eutomer was the same compound for both receptors.⁴¹ Functional antagonism of the 5-HT₃ receptor is demonstrated by inhibition
of the von Bezold-Jarisch reflex in mice for both 12a and ent-12a (87% at 10 mpk for both compounds).

The ethoxy benzamide 12b was prepared in an attempt to increase 5-HT₃ potency, which was successful in boosting 5-HT₃ receptor binding by 6-fold (Kᵢ = 25 nM), however, the compound was approximately 12X less potent in the rat 5-HT₄ TMM assay, so 5-HT₃ receptor binding potency was boosted at the expense of 5-HT₄ potency. The methiodide quaternary ammonium salt 12c was prepared to probe the possibility of synthesizing a potent radiolabeled pyrrolizidine analog employing radiolabeled methyl iodide. The quaternary ammonium salt 12c was indeed very potent in binding to the 5-HT₄ receptor (Kᵢ = 0.35 nM), but despite its greater potency in binding, 12c was markedly less potent than 12a as an agonist in the TMM functional assay, presumably due to membrane transport limitations of the quaternary salt. Compound 13a is the ester corresponding to 12a and was the most potent compound tested in our hands for both 5-HT₄ receptor binding (Kᵢ = 183 pM) and in functional agonism at the 5-HT₄ receptor in the TMM assay (EC₅₀ = 1.5 nM). It is actually a partial agonist at the 5-HT₄ receptor, with 57% efficacy as an agonist relative to serotonin. N-isopropyl benzimidazolone urea 15a, which incorporates the benzimidazolone moiety of BIMU 8 and DAU 6215 exhibited potent binding at the 5-HT₄ receptor (Kᵢ = 7.0 nM) but was 22X less potent in 5-HT₄ agonism than 12a.

The excellent potency of the pyrrolizidine moiety in 5-HT₄ receptor agonism prompted us to consider employing this scaffold for the preparation of antagonists, indeed we were encouraged in this regard by the potent but partial agonism of benzoate ester 13a. Agonism of the 5-HT₄ receptor may be dependent upon a planar array of the amide bond with the aromatic ring system, enabled by an intramolecular H-bond between the amide
NH and the methoxy group as for 12a, or between the amide NH and the benzimidazolone carbonyl of 15a. The 5-HT$_4$ agonist efficacy of ester 13a is lower (57%) apparently due to the inability to form this H-bond and the corresponding conformational mobility.

Table 2 includes pyrrolizidine amides and ureas that are functional 5-HT$_4$ antagonists in the rat TMM assay employing different aromatic groups. All of these compounds were determined to have EC$_{50}$ values for agonism in the rat TMM assay of $>$10,000 nM. Two of the derivatives tested were determined to be inactive in the rat TMM antagonism assay at concentrations of up to 100-1000 nM including indole carboxamide 12d, and indolizine 12e, which borrows the indolizine moiety described by Bermudez. We employed an imidazopyridine aromatic nucleus with the nitrogen lone pair orthogonal to the aromatic pi-system (compounds 12f-i), pointing toward the amide NH in an attempt to mimic the intramolecular hydrogen bond present in the 2-methoxybenzamide prokinetic 5-HT$_4$ agonists. Additionally, we were intrigued that the bridgehead nitrogen lone pair is partially delocalized into the amide carbonyl as in the 4-aminobenzamides 1 and 2, making the carbonyl oxygen more electron rich and favoring coplanarity of the aromatic heterocycle and the amide. The structural similarity to benzofuran amides 4 and 5 is also apparent. Nonetheless we found that these compounds function as 5-HT$_4$ receptor antagonists. Several imidazopyridines afforded good 5-HT$_4$ antagonist activity, including 3-ethylimidazopyridine 12f ($pA_2 = 6.56$). The role of the second nitrogen atom in antagonist imidazopyridine 12f relative to inactive indolizine 12e is noteworthy. The 6-chloro substituent was incorporated in analog 12h to boost binding based on structural overlays done with the benzamide moiety of the prokinetic benzamides, assuming a similar binding mode for the two series based on modeling considerations. Unsubstituted
imidazopyridine 12g was moderately potent (pA₂ = 6.75), whereas addition of the chlorine in the 6-position boosted potency of compound 12h by over an order of magnitude (pA₂ = 8.13). Imidazopyridine 12h exhibited very potent binding to the 5-HT₄ receptor (Kᵢ = 1.4 nM). Incorporation of a 3-methyl substituent was probed in order to augment potency with an additional hydrophobic interaction from the synthetically accessible imidazopyridine, but further substitution with the 3-methyl group decreased the 5-HT₄ inhibitory potency of compound 12i (pA₂ = 7.09) relative to 12h. Oxindole urea 15b, which is structurally related to benzimidazolone 5-HT₄ receptor agonist 15a, is an antagonist that exhibits a pA₂ value of 7.0. As with the imidazopyridines, we originally hoped that the oxindole carbonyl could participate in an intramolecular hydrogen bond with the urea NH. Oxindole 15b exhibits potent binding to the 5-HT₄ receptor (Kᵢ = 6.8 nM).

Pyrrolizidine ester 5-HT₄ receptor antagonists are included in Table 3. The esters were inspired by the work of Buchheit who reported SDZ 205-557, the ester analog of metoclopramide, as the first potent antagonist of 5-HT₄ receptors. These compounds all lack agonist activity in the TMM assay (EC₅₀ >10,000 nM). Based on the inhibitory potency of 6-chloroimidazopyridine amide 12h we prepared the corresponding ester 13b which is a moderate 5-HT₄ receptor antagonist (pA₂ = 6.75). Next, we prepared esters incorporating the indole and indazole aromatic moieties present in tropisetron and granisetron, respectively. Attempted attachment at the indole 2-position afforded N-methyl indole-2-carboxylic ester 13c which was inactive, but good antagonism was obtained with 3-substituted indoles and indazoles, particularly with N-methyl indole-3-carboxylic ester 13d, which exhibited exceptional potency as an antagonist. 5-Methoxyindole-3-carboxylate ester 13e exhibited moderate inhibitory potency at the 5-
HT4 receptor (pA2 = 7.15), and potency was markedly increased for the 5-fluoro derivative 13f in 5-HT4 inhibitory potency (pA2 = 8.5) as well as binding to the 5-HT4 and 5-HT3 receptors (Ki = 700 pM and 10 nM, resp.). Indazole ester 13g had good inhibitory potency (pA2 = 8.48) and the corresponding N-methyl indazole derivative 13h had comparable potency (pA2 = 8.56). These indazoles exhibited potent subnanomolar binding to the 5-HT4 receptor (Ki = 800 pM and 400 pM, respectively), and moderate binding to the 5-HT3 receptor (Ki = 135 nM and 20 nM, respectively). The N-methyl analog was thus modestly more potent than the N-H analog toward both receptors. Both indazoles were free of binding at 5-HT1, 5-HT2, D1, D2, α1, α2, β1, and β2 receptors.

Thus, the most potent member of the pyrrolizidine ester 5-HT4 receptor antagonist series summarized in Table 3 is N-methyl indole-3-carboxylic ester 13d with a pA2 value of 8.93, which is comparable in potency to the Glaxo antagonist GR-113808 (pA2 = 9.39). Indole 13d is a very potent dual receptor 5-HT4/5-HT3 ligand, with a Ki = 183 pM at the 5-HT4 receptor and Ki = 5.0 nM at the 5-HT3 receptor. This pyrrolizidine ester is free of binding at 5-HT1, 5-HT2, D1, D2, α1, α2, β1, and β2 receptors (Ki > 10 uM).

In general, the esters are more potent as 5-HT4 antagonists than the corresponding amides, although the present work only allows for two direct comparators. Specifically, N-methyl indole ester 13d is more potent than the N-methyl indole carboxamide 12d. In contrast, the 6-chloroimidazopyridine amide 12h is more potent than the corresponding ester 13b.

In vivo 5-HT4 agonism was examined in conscious dogs by recording contractile activity of the distal region of the stomach (antrum), as well as along other portions of the gastrointestinal tract. Test compounds were intravenously administered to fasted animals.
during Phase I (a period of quiescence that lasts about 50-80 minutes) of the interdigestive migrating motor complex (MMC). The maximal contractile activity that occurred during Phase III of the MMC was used to normalize the motility response to the compound. Pyrrolizidine amide 12a stimulated sustained antral and jejunal contractile activity as well as a brief augmentation of ileal and colonic contractions (Figure 3).

The antral responses to intravenous dosing of 12a, ent-12a and compound 1 in the canine contractility model are plotted in Figure 4. Pyrrolizidine benzamide 12a exhibited an ED$_{50}$ of 0.010 mg/kg iv, whereas benzamide 1 was 5-fold less potent with an ED$_{50}$ of 0.056 mg/kg iv. Distomer ent-12a was approximately 45X less potent than 12a in promoting gastric antral contractions with an ED$_{50}$ of 0.45 mg/kg iv. A maximally effective dose of pyrrolizidine 12a induced antral contractions which were approximately 60% of the maximum Phase 3 contractions, compared to 54% for compound 1, and 69% for compound 2 (not shown).

In-vivo gastrointestinal prokinetic efficacy was also determined in a functional model for gastroparesis employing gamma scintigraphy. Since 5-HT$_4$ agonists enhance solid gastric emptying largely by increasing the force of contraction of the gastric antrum, the canine antral contractile response was used to select compounds for the gastroparesis model. In the gastroparesis model, an alpha-adrenergic agonist (2-methyl-3-[(2E)-pyrrolidin-2-ylideneamino]phenol) inhibits food-induced gastric antral and duodenal contractions, thus mimicking motor abnormalities characteristic of clinical dysmotilities. Enhancement of gastric emptying in the gastroparesis model is demonstrated by pyrrolizidines 12a, ent-12a and benzamide 1 (Figure 5). Pyrrolizidine benzamide 12a was shown to be approximately 30X more potent than benzamide 1 in enhancing gastric emptying (ED$_{50}$ = 0.001 mg/kg vs. an E$_{D50}$ = 0.03 mg/kg for compound
As expected, distomer ent-12a was less potent than both benzamide 1 and pyrrolizidine 12a, with an ED$_{50}$ of 1.0 mg/kg.

5-HT$_4$ agonism data is summarized in Table 4 along with canine antral contractility and canine solid gastric emptying for the pyrrolizidine benzamides 12a, ent-12a, and the benzamide 1. Pyrrolizidine 12a is the most potent compound in vitro, as well as in vivo in both canine models motility models. Benzamide 1 has an ED$_{50}$ of 55 nM in the rat TMM assay, whereas benzamide 2 exhibits an ED$_{50}$ of 98 nM. Compound 2 is also more potent than benzamide 1 in the antral contractility model, with an ED$_{50}$ of 0.015 mg/kg iv.

Pyrrolizidine derivatives of the present series are highly selective for the 5-HT$_4$ receptor. Pyrrolizidine 12a is very potent as a partial agonist at the 5-HT$_4$ receptor and in binding to the 5-HT$_4$ receptor (Ki = 5.2 nM). Compound 12a exhibits moderate binding at the 5-HT$_3$ receptor (Ki = 152 nM), but no detectible binding (Ki > 10,000 nM) at any of the other monoamine receptors tested (5-HT$_1$, 5-HT$_2$, D$_1$, D$_2$, $\alpha_1$, $\alpha_2$, and $\beta$ receptors). Imidazopyridine 12h, as reported previously, is a very potent antagonist at the 5-HT$_4$ receptor (Ki = 1.4 nM; pA$_2$ = 8.13) with excellent selectivity versus the other monoamine receptors tested (Ki > 10 $\mu$M). Standards included for comparison are compound 6, which we have reported to be a potent and selective dual 5-HT$_4$ agonist and 5-HT$_3$ receptor antagonist, and compound 1, which shows potent inhibition of $\alpha_1$ receptors (Ki = 30 nM) and 5-HT$_2$ receptors (6.1 nM).

In summary, incorporation of the pyrrolizidine scaffold has resulted in the discovery of potent and selective ligands for the 5-HT$_4$ receptor, including the potent and selective 5-HT$_4$ agonist 12a, with excellent efficacy in canine antral motility and gastric emptying models. Toxicological profiling of 12a revealed that the compound is active in the Ames
assay after S9 activation, so the compound was not pursued as a clinical candidate. It is interesting to note that metabolic activation giving rise to mutagenicity appears to be enantiospecific, as the enantiomer ent-12a is not mutagenic with or without S9 activation. The potency and efficacy of this series has prompted analog work to avoid metabolic activation by bridgehead-methyl substitution. It is worth noting in this context that pyrrolizidine 5 is substituted at the bridgehead carbon, which would not permit the formation of a pyrrole-containing metabolite. Nevertheless, pyrrolizidine 12a represents a useful pharmacological tool. Work employing the pyrrolizidine scaffold also resulted in the discovery of imidazopyridine 12h, which is a potent and selective 5-HT₄ receptor antagonist as well as the potent N-methylindole 5-HT₄ receptor antagonist 13d. Related work in these labs on conformationally-constrained amines also led to the discovery of azanoradamantane 6 which is a potent, non-mutagenic and selective dual 5-HT₄ agonist/5-HT₃ antagonist.

**Experimental Section**

(-)-Trachelanthamidine (9). The (S,S)-carbinol (-)-trachelanthamidine 9 was prepared by a diastereoselective alkylation of the chiral tin enolate of 3-(4-chlorobutyryl)-4-(S)-isopropyl-1,3-thiazolidine-2-thione 7 with 5-acetoxy-2-pyrrolidinone and subsequent reduction with lithium aluminum hydride as described by Yoshimitsu Nagao to afford 9 (3.12 g, 45.5%) as a colorless oil: [α]D = +9.2 (c = 0.195 g/dL in CHCl₃; 10 cm); [α]365 = -63.1 (c = 0.195 g/dL in CHCl₃; 10 cm). The Mosher ester was prepared by treatment of the alcohol with the Mosher acid chloride [from (S)-(−)-α-methoxy-α-(trifluoromethyl)phenylacetic acid and thionyl chloride] and pyridine. ¹⁹F NMR analysis
of the peak at -172.17 ppm and the absence of the peak at -172.29 ppm from the
diastereomeric standard showed that the material was $\geq 99.6\%$ diastereomeric purity, or
$\geq 99.1\%$ e.e.

2-[(1S,7aS)-Hexahydro-1H-pyrrolizin-1-ylmethyl]-1H-isoindole-1,3(2H)-dione (10). To a solution of alcohol 3 (1.44 g, 10.2 mmol) in dry THF (45 mL) was added
triphenylphosphine (5.35 g, 20.4 mmol) and phthalimide (3.00 g, 20.4 mmol). The
solution was then cooled to 0°C and diethylazodicarboxylate (3.21 mL, 3.55 g, 10.4
mmol) was added dropwise over 15 minutes. The reaction was then stirred for 1 h at 0°C
and then 16 h at rt. Concentration gave a residue which was purified on silica gel eluting
with MeOH (saturated with NH$_3$)/CHCl$_3$ (4/96, then 6/94) to afford the desired
phthalimide 10 (2.12 g, 82%) as a pale yellow crystalline solid: mp 72-73°C; IR (MIR)
1763, 1706.5 cm$^{-1}$. [$\alpha$]$_D$ = -2.5°; [$\alpha$]$_{365}$ = -13.3° (c = 0.285 g/dL in chloroform). $^1$H
NMR (300 MHz, CDCl$_3$) $\delta$ 7.86 (2H, m), 7.73 (2H, m), 3.76 (2H, d, J = 7.1 Hz), 3.28

(1S,7aS)-Hexahydro-1H-pyrrolizin-1-ylmethylamine dihydrochloride (11). To a
solution of phthalimide 10 (4.11 g, 15.2 mmol) in ethanol (60 mL) was added hydrazine
hydrate (3.70 g, 74 mmol) and the reaction was stirred for 15 h at rt. The resulting
suspension was concentrated to give a residue. To the residue was added 4 N KOH (50
mL, presaturated with NaCl) and the mixture was extracted with chloroform (15 X 20
mL). The combined extracts were dried over sodium sulfate and concentrated to give the
title amine 11 (2.13 g, 100%) as a yellow semisolid, which may be stored under argon at -30°, if necessary, before use in the subsequent step. ¹H NMR (300 MHz, CDCl₃) δ 3.13 (2H, m), 2.95 (1H, m), 2.74 (2H, m), 2.56 (2H, m), 2.03 (1H, m), 1.98-1.63 (4H, m), 1.62 – 1.43 (2H, m). Dihydrochloride salt of 11: ¹H NMR (300 MHz, d₄-MeOD) δ 3.97 (1H, m), 3.79 (1H, m), 3.46 (1H, m), 3.29-3.03 (3H, m), 2.51–2.34 (2H, m), 2.32 – 1.78 (5H, m). ¹³C NMR (75 MHz, d₄-MeOD) δ 70.4, 54.4, 53.9, 42.5, 40.7, 29.8, 29.4, 24.3.

HRMS MH⁺ calcd for C₈H₁₆N₃ 141.1392, found 141.1394.

4-Amino-5-chloro-N-[(1S-cis-hexahydro-1H-pyrrolizin-1-yl)methyl]-2-
methoxybenzenecarboxamide, hydrochloride (12a, SC-53116). To a solution of 4-
acetamido-5-chloro-2-methoxy-benzoic acid (3.70 g, 15.2 mmol) in DMF (15 mL, freshly
distilled under high vacuum) was added 1,1'-carbonyldiimidazole (2.46 g, 15.2 mmol)
which resulted in a vigorous gas evolution. After 40 min at rt a solution of the free base
amine 11 (2.13 g, 15.2 mmol) in DMF (6 mL) was added and reaction was stirred for 40 h
at rt. Concentration gave a yellow oil which was treated with 15% K₂CO₃ (65 mL) and
extracted with chloroform (4X). The combined organic extracts were washed
successively with water (2X) and brine and dried over sodium sulfate to give a pale
yellow solid (5.9 g). Purification on silica gel (170 g) eluting with MeOH (saturated with
NH₃)/CHCl₃ (15/85) gave 4-(acetylamino)-N-[(7aS)-hexahydro-1H-pyrrolizin-1-
ylmethyl]-5-chloro-2-methoxybenzamide (4.89 g, 88%) as a colorless solid after drying
for 1 h at 100°C: mp 131-132°C; [α]D = -8.8° (c = 1.2 g/dL); IR (MIR) 3407, 3310, 1696,

[α]D = -2.6°; [α]365 = -6.4° (c = 0.47g/dL in methanol).

Amide Coupling General Procedure. We have found that benzamide couplings utilizing 4-amino-5-chloro-2-methoxy-benzoic acid generally proceed very well without acetamide protection of the 4-amino group. According to this general procedure, to a solution of carboxylic acid (1 equivalent) in DMF (freshly opened) is added 1,1'-carbonyldiimidazole (1 equivalent) which results in a vigorous gas evolution. After 0.5 to 1 h at rt a solution of the amine 11 in DMF is added and reaction is stirred for 2 h at rt followed by 2 h at 50°C. Concentration affords a residue which is treated with 15% K₂CO₃ and extracted with chloroform (3X). The combined organic extracts are washed successively with water (2X) and brine and dried over sodium sulfate. Concentration affords the desired product which may be purified by crystallization or may be pure enough to carry on directly to the hydrochloride salt formation as described above for 12a. Alternatively, purification on silica gel eluting with MeOH (saturated with NH₃)/CHCl₃ (15/85) affords the pure coupled material as the free base which is then converted to the hydrochloride salt.
4-Amino-5-chloro-N-[(1R,7aR)-hexahydro-1H-pyrrolizin-1-ylmethyl]-2-methoxybenzamide (ent-12a, SC-53117). This compound was prepared from (+)-trachelanthamidine, prepared according to the method of Nagao\textsuperscript{38} and continued as above for the enantiomeric series beginning with 3-(4-chlorobutyryl)-4-(R)-isopropyl-1,3-thiazolidine-2-thione to afford ent-12a: Analysis calculated for C\textsubscript{16}H\textsubscript{22}N\textsubscript{3}O\textsubscript{2}Cl:1.2HCl:0.8H\textsubscript{2}O: C, 50.31; H, 6.54; N, 11.00; Cl, 20.42. N-[(1S,7aS)-Hexahydro-1H-pyrrolizin-1-ylmethyl]-1-methyl-1H-indole-3-carboxamide (12d). To a solution of N-methylindole-3-carboxylic acid (1.0 eq) in DMF at rt was added CDI (1 eq). After 1 h a solution of amine 11 (1 eq) in DMF was added and the solution stirred for 16 h at rt. Aqueous workup and chromatography on silica gel afforded the desired indole carboxamide 12d: C$_{18}$H$_{23}$N$_3$O Anal calcd for C$_{18}$H$_{23}$N$_3$O: C, 72.70; H, 7.80; N, 14.13. Found C, 72.91; H, 7.68; N, 13.92.

N-exo(Tetrahydro-1H-pyrrolizin-4(5H)-ylmethyl)-3-ethylindolizine-1-carboxamide (12e). 3-Ethylindolizine-1-carboxylic acid$^{44}$ (190 mg, 1.0 mmol) was suspended in CHCl$_3$ (2 mL). Oxalyl chloride (184 uL, 2.1 mmol) and DMF (1 drop) were added and the mixture stirred for 2 h. The reaction mixture was concentrated in vacuo, azeotroping once with toluene. To the residue dissolved in CHCl$_3$ was added a solution of exo-tetrahydro-1H-pyrrolizin-4(5H)-methylamine 11 (140 mg, 1.0 mmol), and triethylamine (279 uL, 2.0 mmol) in CHCl$_3$ (2 mL) and the mixture was stirred for 18 h. The organic solution was washed with 1N NaOH, brine, dried over K$_2$CO$_3$, filtered and concentrated to give a crude oil. Purification on silica gel eluting with MeOH (saturated with NH$_3$)/CHCl$_3$ (30/70) gave the desired compound 12e as a very hydroscopic solid (190 mg, 63%). $^1$H NMR (400 MHz, d$_4$-MeOD) δ 8.20 (1H, d, J= 18 Hz), 8.02 (1H, t, J=
14 Hz), 7.03 to 6.97 (3H, m), 6.80 to 6.75 (1H, m), 4.06 to 3.99 (1H, m), 3.83 to 3.75 (1H, m), 3.67 (2H, d, J= 6 Hz), 3.46 to 3.42 (1H, m), 3.25 to 3.18 (1H, m), 3.18 to 3.03 (1H, m), 2.54 to 2.45 (1H, m), 2.37 to 2.29 (1H, m), 2.22 to 2.12 (2H, m), 2.09 to to1.86 (3H, m). Anal calcd for C$_{19}$H$_{25}$N$_{3}$O:2.0 H$_{2}$O: C, 65.68; H, 7.25; N, 12.09. Found C, 65.79; H, 7.56; N, 12.03. MS calcd for C$_{19}$H$_{25}$N$_{3}$O: 311.43, Found: 311.19. Attempts to make the HCl salt resulted in a brown oil, so the compound was tested as the free base.

**N-exo(tetrahydro-lH-pyrrolizin-4(5H)-ylmethyl)-3-ethylimidazo[1,2-a]pyridine-l-carboxamide monohydrochloride (12f).** 3-Ethylimidazo[1,5-a]pyridine-l-carboxylic acid$^{44}$ (190 mg, 1.0 mmol) was suspended in CHCl$_3$ (2 mL). Oxalyl chloride (184 µL, 2.1 mmol) and DMF (1 drop) were added and mixture stirred for 2 h. The reaction mixture was concentrated in vacuo, azeotroping once with toluene. To the residue dissolved in CHCl$_3$ was added a solution of exo-tetrahydro-lH-pyrrolizin-4(5H)-methylamine 11 (140 mg, 1.0 mmol) and triethyl amine (279 µL, 2.0 mmol) in CHCl$_3$ (2 mL) and the mixture stirred for 18 h. The organic solution was washed with 1N NaOH, brine, dried over K$_2$CO$_3$, filtered and concentrated to give a crude oil which was chromatographed on silica gel eluting with 5% CH$_3$OH(NH$_3$)/CHCl$_3$ to give 110 mg (35%) of desired compound as the free base. The HCl salt 12f was prepared in the same manner as for 12a: Anal calcd for C$_{18}$H$_{24}$N$_{4}$O.HCl:0.75H$_2$O C, 57.91; H, 7.24; N, 15.01; Cl, 12.35. N-exo((4-s,7αα αα)-Tetrahydro-1H-pyrrolizin-4(5H)-yl)-6-chloroimidazo[1,2-
a]pyridine-3-methyl-8-carboxamide (12i). A suspension of 2-aminonicotinic acid 16 
(5.0 g; 0.036 mol) and K_{2}CO_{3} (5.0 g; 0.36 mol) in DMF (50 mL) were heated to reflux, 
and then the solution was cooled to ambient temperature. Iodomethane (5.1 g, 2.2 mL, 
0.036 mol) was then added to the mixture and the solution was stirred for 18 h. The 
mixture was filtered and concentrated. The residue was filtered through a pad of silica, 
eluting with 5/95 EtOH/CH_{2}Cl_{2} containing 0.1% NH_{4}OH. The resulting solution was 
concentrated and the residue was suspended in Et_{2}O, filtered and concentrated to yield 
methyl 2-aminonicotinate (3.2 g).

The methyl 2-aminonicotinate (800 mg, 0.00525 mol) was dissolved in MeOH (15 
ml). HCl gas was passed over the solution until the solution was acidic (pH 2), then the 
solution was concentrated. The residue was dissolved in MeOH (15 mL) and t-
butylhypochlorite (570 mg, 5.25 mmol) was added to the reaction mixture and stirred 
until the yellow color dissipated. Additional t-butyl hypochlorite was added until tlc (5/95 
EtOH/CH_{2}Cl_{2} containing 0.1% NH_{4}OH) indicated that the starting material was 
consumed. The reaction mixture was concentrated and the residue was partitioned 
between CH_{2}Cl_{2} and 5% aqueous NaHCO_{3}. The organic layer was washed with 5% 
aqueous sodium thiosulfate, dried over MgSO_{4} and concentrated. The solid residue was 
suspended in 1:1 CH_{2}Cl_{2}/hexane, filtered, washed with hexane, and suction dried to yield 
methyl 2-amino-5-chloronicotinate 20 (250 mg, 26%): mp 139-40°C. Anal calcd for
Methyl 2-amino-5-chloronicotinate 20 (7.0 g, 0.045 mol) and 2-bromopropionaldehyde (15.8 g, 0.116 mol) were combined in EtOH (100 mL) and refluxed until tlc (5/95 EtOH/toluene containing 0.1% NH₄OH) indicated that the starting material was consumed. The reaction mixture was concentrated and the residue was triturated with acetone, then partitioned between CH₂Cl₂ and 5% aqueous K₂CO₃. The organic layer was dried over MgSO₄ and concentrated. The residue was triturated with Et₂O to yield methyl 6-chloroimidazo[1,2-a]pyridine-3-methyl-8-carboxylate (5.0 g, 50%) as a solid: IR: 1720 cm⁻¹. Anal calcd for C₁₀H₉ClN₂O₂ C: 53.47; H: 4.04; N: 12.47; Cl: 15.78. Found: C: 53.14; H: 4.06; N: 12.37; Cl: 16.03. MS MH⁺ calcd for C₁₀H₇ClN₂O₂ 225, found 225.

The methyl 6-chloroimidazo[1,2-a]pyridine-3-methyl-8-carboxylate (5.0 g; 0.022 mol) was suspended in 6N HCl (50 mL) and heated to reflux for 2 h. The reaction mixture was concentrated to near dryness. The residue was suspended in acetone and the solid filtered and washed with acetone to yield 6-chloroimidazo[1,2-a]pyridine-3-methyl-8-carboxylic acid 21 (4.9 g) as the HCl salt: IR: 1704 and 3175 cm⁻¹. Anal calcd for C₉H₇ClN₂O₂.HCl C: 43.75; H: 3.26; N: 11.34; Cl: 28.70. Found: C: 43.54; H: 3.16; N: 11.26; Cl: 28.74. MS MH⁺ calcd for C₉H₇ClN₂O₂ 211, found 211.

To a solution of 6-chloroimidazo[1,2-a]pyridine-3-methyl-8-carboxylic acid 21 (247 mg, 1.00 mmol) in DMF (5 mL) was added 1,1’-carbonyldiimidazole (178 mg, 0.011 mol) and the solution stirred for 1 h. Aminomethylpyrrolizidine 11 (120 mg, 0.85 mmol) and Et₃N (560 µL, 4.0 mmol) were added to the reaction mixture and the solution was stirred for 1 h before concentrating. The residue was partitioned between CHCl₃ and 5% aqueous K₂CO₃. The organic layer was dried over Na₂SO₄ and concentrated. The residue
was purified by preparative thin-layer chromatography eluting with 20/80 MeOH/CHCl₃ containing 0.25% NH₄OH. The filtrate was concentrated and the residue was dissolved in CHCl₃ and filtered through celite and concentrated to yield an oil (144 mg, 43%). This residue was converted to the HCl salt the desired imidazopyridine amide 12i using a mixture of acetyl chloride/MeOH. ¹H NMR (400 MHz, d₄-MeOD) δ 9.10 (1H, d, J= 2.5 Hz), 8.56 (1H, d, J= 2.5 Hz), 7.89 (1H, d, J=1 Hz), 4.08 to 4.03 (1H, m), 3.81 to 3.75 (1H, m), 3.63 (2H, d, J= 6 Hz), 3.51 to 3.45 (1H, m), 3.22 to 3.19 (1H, m), 3.16 to 3.09 (1H, m), 2.68 (3H, d, J= 1 Hz), 2.52 to 2.46 (1H, m), 2.35 to 2.27 (1H, m), 2.25 to 2.14 (2H, m), 2.09 to 2.03 (1H, m), 1.99 to 1.87 (2H, m). (1R,7aS)-Hexahydro-1H-pyrrolizin-1-ylmethyl 4-amino-5-chloro-2-methoxybenzoate hydrochloride (13a). To NaH solid (52 mg of 60% dispersion, washed with hexane, 31 mg NaH) was added a solution of alcohol 9 (185 mg, 1.31 mmol) in DMF (2 mL) at 0°C. After the effervescence was complete (0.5 h) this sodium alcoholate was added to the imidazolide of 4-amino-5-chloro-2-methoxybenzoic acid [330 mg, 1.31 mmol at 0°C. [The imidazolide was prepared by the addition of CDI (656 mg, 4.05 mmol) to 4-amino-5-chloro-2-methoxybenzoic acid (800 mg, 3.97 mmol). Aqueous workup and recrystallization from ether/CHCl₃ afforded the requisite imidazolide (780 mg, 78%) as colorless crystals, mp 122-122.5°C.] The reaction was allowed to warm to rt over 2 h. Water was added and the mixture extracted with CHCl₃. The combined organic extracts were washed with water (2X) and brine and dried over Na₂SO₄. Concentration gave a solid (362 mg) which was purified by chromatography on
silica gel eluting with i-PrOH(NH$_3$)/CHCl$_3$ to afford the free base ester (129 mg, 30%).

To a solution of the free base (117 mg, 0.36 mmol) in MeOH (1.5 mL) was added HCl/MeOH [prepared by the addition of acetyl chloride (23 uL, 25 mg, 0.36 mmol) to MeOH (1.5 mL) to afford the desired monohydrochloride salt of ester 13a (98 mg, 72%) as a beige solid: mp 191-193°C. HRMS calcd for C$_{16}$H$_{21}$N$_2$O$_3$Cl 325.1319, found 325.1298. Anal calcd for C$_{16}$H$_{21}$N$_2$O$_3$Cl: HCl:0.25H$_2$O C, 52.54; H, 6.20; N, 7.66; Cl, 19.39. Found C, 52.44; H, 6.06; N, 7.66; Cl, 19.18. $^1$H NMR (300 MHz, d$_4$-MeOD) δ 7.73 (1H, s), 6.48 (1H, s), 4.37 (1H, dd, J = 11.3, 5.4 Hz), 4.28 (1H, dd, J = 11.3, 6.6 Hz), 4.06 (1H, m), 3.82 (3H, s), 3.78 (1H, m), 3.48 (1H, m), 3.29 – 3.10 (2H, m), 2.54 (1H, m), 2.38 – 1.85 (6H, m). $^{13}$C NMR (75 MHz, d$_4$-MeOD) δ 166.3, 162.0, 151.6, 134.0, 110.4, 108.0, 98.8, 71.8, 64.9, 56.3, 55.9, 55.6, 45.3, 31.0, 30.1, 25.6.

(1R,7aS)-Hexahydro-1H-pyrrolizin-1-ylmethyl 6-chloroimidazo[1,2-a]pyridine-8-carboxylate (13b). To NaH (91 mg of 60%, 2.30 mmol, washed with hexane) was added a solution of alcohol 9 (162 mg, 1.15 mmol) in DMF (2 mL) at 0°C. After 0.5 h the solution of this sodium salt was added to the imidazolide of imidazopyridine carboxylic acid [prepared by adding added CDI (186 mg, 1.15 mmol) to a solution of 6-chloroimidazo[1,2-a]pyridine-8-carboxylic acid 19 (267 mg, 1.15 mmol) in DMF (2 mL) at 0°C.] After 0.5 h at 0°C the solution was allowed to warm to rt over 3 h. Concentration gave a residue that was quenched with water (20 mL) and extracted with CHCl$_3$ (3X). The combined organic extracts were washed with water (2X) and brine and dried over Na$_2$SO$_4$. Concentration gave a pale yellow oil (210 mg) which was purified by recrystallization from EA to afford the desired pyrrolizidine ester free base (155 mg, 42%) as yellow crystals: mp 116-117°C. IR (MIR) 3100, 1690, 1537, 1494, 1307, 1277
$^1$H NMR (300 MHz, CDCl$_3$) $\delta$ 8.65 (1H, d, J = 1.8 Hz), 7.88 (1H, d, J = 1.8 Hz), 7.80 (1H, s), 7.65 (1H, s), 4.46 (2H, m), 3.36 (1H, q, J = 6.5 Hz), 3.23 (1H, t, J = 7.6 Hz) 3.00 (1H, dt, J = 10.2, 5.9 Hz), 2.60 (2H, m), 2.21 (1H, m), 2.14 (1H, m), 1.98 (1H, m), 1.90 – 1.73 (3H, m), 1.62 (1H, m). To a solution of this free base (89.1 mg, 0.28 mmol) was added HCl/MeOH [prepared by the addition of acetyl chloride (17.8 uL, 19.6 mg, 0.279 mmol) to MeOH (1.5 mL)]. After 1 h at rt the solution was concentrated and the resulting solid was triturated with EA and then dried to afford the requisite imidazopyridine ester 13b (92 mg, 92%) as an off-white powder: mp 192°C (dec); IR (MIR) 3400, 3093, 2969, 2479, 1721, 1543, 1304, 1282, 1187 cm$^{-1}$. $^1$H NMR (300 MHz, d$_4$-MeOD) $\delta$ 8.99 (1H, d, J = 1.8 Hz), 8.14 (1H, d, J = 1.4 Hz), 8.07 (1H, d, J = 1.1 Hz), 7.83 (1H, s), 4.57 (1H, dd, J = 11.1, 3.5 Hz), 4.48 (1H, dd, J = 11.1, 2.3 Hz), 4.29 (1H, td, J = 8.8, 0.8 Hz), 3.84 (2H, AB m), 3.55 (1H, m), 3.22 (1H, m), 2.91 (1H, m), 2.63 (1H, m), 2.46 – 1.87 (4H, m). $^{13}$C NMR (75 MHz, d$_4$-MeOD) $\delta$ 164.3, 142.1, 134.7, 133.1, 131.1, 121.2, 119.6, 116.2, 72.1, 70.7, 55.4, 55.2, 42.7, 30.3, 29.2, 24.6. 1-Methyl-1H-indole-2-carboxylic acid-(1R,7aS)-1-(hexahydro-pyrrolizin-1-yl)methyl ester (13c). To indole 2-carboxylic acid (186 mg, 1.06 mmol) dissolved in DMF (2.5 mL) was added 1,1’-carbonyldiimidazole (172 mg, 1.06 mmol) at ambient temperature and stirred. After 1.5 h alcohol 3 (150 mg, 1.06 mmol) in DMF (0.5 mL) was added and the reaction was stirred for 16 h. Solvent was evaporated to give the desired ester as an oil. Purification on silica gel eluting with MeOH (saturated with NH$_3$/CHCl$_3$ (10/90) gave the ester (170 mg, 53%) as a solid: $^1$H NMR (300 MHz, CD$_3$OD) $\delta$ 7.68 (m, 1H),
7.37 (d, 2H), 7.35 (d, 1H), 7.16 (t, 1H), 7.10 (s, 1H), 4.64 (dd, 2H), 4.09 (m, 1H), 3.37 (q, 1H), 3.24 (t, 1H), 3.00 (m, 1H), 2.61 (m, 2H), 2.20-1.77 (m, 6H), 1.964 (septet, 1H). To a solution of this free base (150 mg, 0.50 mmol) was added HCl/MeOH [prepared by the addition of acetyl chloride (72 µL, 1.00 mmol) to MeOH]. After 1 h at rt the solution was concentrated and resulting solid was triturated with diethyl ether and then dried to give the desired hydrochloride salt 13c (140 mg, 83%). 1H NMR (300 MHz, CD3OD) δ 7.64-7.56 (d, 1H), 7.49 (d, 1H), 7.35 (d, 1H), 7.33 (s, 1H), 7.12 (t, 1H); 4.44 (qq, 2H), 4.10 (m, 1H), 4.05 (s, 3H), 3.82 (m, 1H), 3.49 (m, 1H), 3.26-3.18, (m, 2H); 2.62 (m, 1H), 2.36 (m, 2H), 2.21-2.29 (m, 2H), 1.98-2.02 (m, 2H). HRMS calcd for C18H22N2O2 298.1673, found 298.1686.

(1R,7aS)-Hexahydro-1H-pyrrolizin-1-ylmethyl 1-methyl-1H-indole-3-carboxylate (13d). To N-methylindole-3-carboxylic acid53 (2.0 g, 11 mmol) in DMF (10 mL) was added 1,1’-carbonyldiimidazole (1.78 g, 11 mmol) and the solution was stirred at rt for 3h. Water (20 mL) and ice (30 g) were added and the mixture was extracted with chloroform (3X). The combined organic extracts were washed with brine and dried over magnesium sulfate. Concentration gave the intermediate imidazolide (2.4 g, 93%) which was used directly.

To a suspension of sodium hydride (312 mg of 60% NaH, 7.8 mmol; washed with hexane) in DMF (5 mL) at 0°C was added a solution of alcohol 9 (1.1 g, 7.8 mmol) in DMF (6 mL). The resulting mixture was stirred at 0°C for 0.5 h after which time a solution of the imidazolide (1.76 g, 7.8 mmol) in DMF (5 mL) was added. The reaction was allowed to warm to rt for 16 h. The mixture was then concentrated to give a solid which was chromatographed on silica gel (50 g) eluting with MeOH (saturated with
NH3)/CHCl3 (5/95) to give the free base of 13d (2.03 g, 87%). To a solution of this free base (2.0 g, 6.70 mmol) in methanol (10 mL) was added methanolic HCl [prepared by the addition of acetyl chloride (0.48 mL, 6.7 mmol) to methanol (10 mL) at 0°C]. Concentration gave a foam which was redissolved in a minimum amount of methanol and added dropwise to diethyl ether (700 mL) with vigorous stirring. Filtration gave a beige solid (2.02 g) which contained the desired indole carboxylate as well as imidazole hydrochloride. This material was recrystallized from diethyl ether/ethanol to give the title compound 13d (1.19 g, 60%) as a colorless solid: $^1$H NMR (400 MHz, d$_4$-MeOD) δ 8.45 (1H, d, J= 6 Hz), 8.00 (1H, s), 7.46 (1H, d J= 6 Hz), 7.3 to 7.2 (2H, m), 4.45 to 4.34 (2H, m), 4.14 to 4.08 (1H, m), 3.862 (3H, s), 3.83 to 3.77 (1H, m), 3.51 to 3.45 (1H, m), 3.26 to 3.13 (2H, m), 2.64 to 2.55 (1H, m), 2.38 to 2.30 (1H, m), 2.27 to 2.15 (2H, m), 2.11 to 1.93 (3H, m). Analysis calculated for C$_{18}$H$_{22}$N$_2$O$_2$.HCl: C, 64.61; H, 6.92; N, 8.37; Cl, 10.59. Found C, 64.31; H, 7.24; N, 8.65; Cl, 10.95. Purity by HPLC 99.9%.

(1R,7aS)-Hexahydro-1H-pyrrolizin-1-ylmethyl 5-methoxy-1H-indole-3-carboxylate hydrochloride (13e). To 5-methoxyindole-3-carboxylic acid (203 mg, 1.06 mmol) dissolved in DMF (2.5 mL) was added 1,1’-carbodiimidazole (172 mg, 1.06 mmol) at ambient temperature. After 1.5 hours alcohol 9 (150 mg, 1.06 mmol) in DMF (0.5 mL) was added and the reaction was stirred for 16 h. The solvent was concentrated to afford an oil. Purification on silica gel (20 g) eluting with MeOH (saturated with NH$_3$)/CHCl$_3$ (10/90) gave the ester as a solid (120 mg, 36%). To a solution of this free base (110 mg, 0.35 mmol) was added HCl/MeOH [prepared by the addition of acetyl chloride (50 µl, 0.70 mmol) to MeOH]. After 1 h at rt the solution was concentrated and resulting solid was triturated with diethyl ether and then dried to give the desired
hydrochloride salt 13e (56 mg, 46%). $^1$H NMR (300 MHz, CD$_3$OD) $\delta$ 7.95 (s, 1H), 7.54 (d, 1H), 7.32 (d, 1H), 6.87 (dd, 1H), 4.41 (m, 2H), 4.09 (m, 1H), 3.84 (s, 3H), 3.79 (m, 1H), 3.49 (m, 1H), 3.19 (m, 2H), 2.61 (m, 1H), 2.36 (m, 2H), 2.21 (m, 2H), 2.03 (m, 2H).

cis-N-[(Hexahydro-1H-pyrrolizin-1-yl)methyl]-2,3- dihydro-3-(1-methylethyl)-2-oxo-lH-benzimidazole-l-carboxamide (15a). A dispersion of 60% NaH/mineral oil (80 mg, 0.002 mol) was washed with hexane and suspended in THF. Solid 1,3-dihydro-1-(1-methylethyl)-2H-benzimidazol-2-one$^{54}$ (176 mg, 1.00 mmol) was added to the suspension. This mixture was stirred 15 minutes before adding to a solution of 2.5 mL (0.004 mol) of 20% phosgene in toluene/2.5 mL THF. The resulting mixture was filtered through celite and concentrated. The residue was dissolved in THF (5.0 mL) and a solution of aminomethylpyrrolizidine 11 (140 mg, 1.0 mmol) was added in Et$_3$N (0.5
mL). This mixture was stirred for 1 h, filtered and concentrated. The residue was purified by preparative thin-layer chromatography eluting with 30/70 MeOH/CHCl₃ containing 0.25% NH₄OH. The product was rinsed from the silica with 9/95 NH₄OH/MeOH. The filtrate was concentrated and the residue was dissolved in CHCl₃ and filtered through celite and concentrated to afford the benzimidazolone 15a (157 mg, 50%). The product was converted to the HCl salt by dissolving 36 uL of acetyl chloride in 5.0 mL of MeOH and adding this solution to the product, then concentrating to dryness: ¹H NMR (400 MHz, d₄-MeOD) δ 8.11 (1H, dd, J= 8.1, 0.8 Hz), 7.32 (1H, dd, J= 8.1, 0.8 Hz), 7.22 (1H, d of t, J= 8.1, J= 1 Hz), 7.13 (1H, d of t, J= 8.1, J= 1 Hz), 4.70 (1H, sep, J= 7 Hz), 4.04 to 3.96 (1H, m), 3.82 to 3.74 (1H, m), 3.58 to 3.55 (2H, m), 3.50 to 3.42 (1H, m), 3.25 to 3.18 (1H, m), 3.16 to 3.08 (1H, m), 2.49 to 2.39 (1H, m), 2.36 to 2.26 (1H, m), 2.25 to 2.17 (1H, m), 2.11 to 2.03 (1H, m), 2.01 to 1.93 (1H, m), 1.91 to 1.82 (1H, m), 1.54 (2H, d, J= 7 Hz). exo-2,3-Dihydro-3,3-dimethyl-N-[(hexahydro-lH-pyrrolizin-1S-yl)methyl]-2-oxo-1H-indole-1-carboxamide, hydrate hydrochloride (15b). To sodium hydride (214 mg, 5.6 mmol, washed 2X with hexane) suspended in THF (1 mL) was added 1,3-dihydro-3,3-dimethyl-2H-indol-2-one⁵⁵ (226 mg, 1.4 mmol) and the reaction was stirred for 10 minutes. The resulting suspension was added to a solution of 20% phosgene in toluene (5.50 mL, 11.2 mmol) in THF (5 mL) and the reaction was stirred for 1 hour. The reaction mixture was filtered through celite and concentrated in vacuo to give an oil. To a solution of the oil in THF (5 mL) was added a solution of aminomethylpyrrolizidine 11 (200 mg, 1.4 mmol) and triethylamine (200 uL, 1.4 mmol) in THF (2 mL) and the
reaction was stirred for 18 hours. The solution was then diluted with chloroform, washed with saturated K$_2$CO$_3$ solution, dried over K$_2$CO$_3$, filtered and concentrated in vacuo to give crude desired product as an oil. Purification on silica gel eluting with 10% CH$_3$OH(NH$_3$)/CHCl$_3$ gave the free base of the benzimidazolone (193 mg, 42%) as a solid: Analysis calculated for C$_{19}$H$_{25}$N$_3$O$_2$:0.4H$_2$O C, 68.19; H, 7.77; N, 12.56. Found C, 68.06; H, 7.74; N, 12.44. HRMS calculated for C$_{19}$H$_{25}$N$_3$O$_2$: 327.1947, found 327.1930. The free base (180 mg, 0.550 mmol) was converted to the hydrochloride salt by treatment with methanolic HCl to give the hydrochloride salt 15b (128 mg, 64%) as a solid: $^1$H NMR (400 MHz, d$_4$-MeOD) $\delta$ 8.10 (1H, d, J= 2 Hz), 7.33 (1H, d, J= 2Hz), 7.28 (1H, t, J= 2 Hz), 7.19 (1H, t, J= 2 Hz), 4.02 to 3.96 (1H, m), 3.79 to 3.74 (1H, m), 3.53 (2H, d, J= 6.4 Hz), 3.49 to 3.43 (1H, m), 3.24 to 3.18 (1H, m), 3.15 to 3.08 (1H, m), 2.48 to 2.38 (1H, m), 2.33 to 2.25 (1H, m), 2.22 to 2.13 (2H, m), 2.08 to 1.02 (1H, m), 1.99 to 1.92 (1H, m), 1.90 to 1.83 (1H, m), 1.41 (6H, s). MS calculated for C$_{19}$H$_{25}$N$_3$O$_2$: 327.1947, found: 327.1939.

Imidazol[1,2-a]pyridine-8-carboxylic acid monohydrochloride (17). 2-Aminonicotinic acid 16 (14.1 g; 0.102 mol) and chloroacetaldehyde [45% aqueous solution] (8.6 g, 100 mmol) were dissolved in EtOH (100 mL) and heated to reflux. The reaction was monitored by tlc with 30% MeOH/CH$_2$Cl$_2$/1.0% HOAc, and additional chloroacetaldehyde was added until the starting material was consumed. The reaction mixture was concentrated and the solid filtered and washed with EtOH and suction dried to yield imidazol[1,2-a]pyridine-8-carboxylic acid monohydrochloride 17 (17.5 g, 88%) as a solid: IR: 1582, 1651, 1687, 3049 and 3320 cm$^{-1}$. Anal calcd for C$_8$H$_6$N$_2$O$_2$.HCl 48.38; H: 3.55; N: 14.10; Cl: 17.85. Found: C: 48.16; H: 3.59; N: 13.95; Cl: 17.50.
6-Chloroimidazo[1,2-a]pyridine-8-carboxylic acid (19). Methyl 2-amino-5-chloronicotinate 18 (7.0 g; 0.045 mol) and 45% aqueous chloroacetaldehyde (10.5 g; 0.06 mol) were dissolved in EtOH (100 mL) and heated to reflux for 3 h. The reaction mixture was concentrated and the solid filtered and washed with EtOH and suction dried to yield methyl 6-chloroimidazo[1,2-a]pyridine-8-carboxylate (9.5 g, 80%) as a solid. Anal calcd for C_{9}H_{7}N_{2}O_{2}.HCl.H_{2}O: C: 40.78; H: 3.80; N: 10.57; Cl: 26.75. Found: C: 40.68; H: 3.74; N: 10.19; Cl: 26.85.

The methyl 6-chloroimidazo[1,2-a]pyridine-8-carboxylate (9.5 g, 0.036 mol) was combined with 6N HCl (100 mL) and heated to reflux for 2 h. The reaction mixture was concentrated to near dryness. The residue was suspended in acetone and the solid filtered and washed with acetone to yield 6-chloroimidazo[1,2-a]pyridine-8-carboxylic acid hydrochloride salt (6.3 g, 75.5%) as a solid: IR: 1679 and 3281 cm\(^{-1}\). Anal calcd for C_{8}H_{5}N_{2}O_{2}.HCl: C: 41.23; H: 2.60; N: 12.02; Cl: 30.42. Found: C: 40.95; H: 2.43; N: 12.16; Cl: 30.67.

(+)-4-Amino-5-chloro-N-(hexahydro-2,5ββββ-methano-1H-3aS,3aαααα,6aαααα-cyclopenta[c]pyrrol-4α-y)-2-methoxybenzamide, monohydrochloride (6, SC-52491).

Compound 6 was prepared initially by synthesis involving resolution as previously described\(^{41}\) then via an enantioselective synthesis commencing with an asymmetric Diels-Alder reaction.\(^{52}\)

Serotonin 5-HT\(_{3}\) Receptor Binding

Displacement of \[^{3}\text{H}\]-GR65630 from brain cortex obtained from male Wistar rats was done by the method of Kilpatrick.\(^{56}\) Cortical membrane preparations (0.04 mg) were incubated with 0.2 nM \[^{3}\text{H}\]-GR65630 in the presence or absence of graded
concentrations test compound for 60 min at 22°C. One micromolar of tropisetron was used for nonspecific binding to the membranes. Membranes were filtered, washed three times and counted to obtain binding displacement curves and determine specific binding of [3H]-GR65630 to the 5-HT₃ receptor.

**Serotonin 5-HT₄ Receptor Binding**

Serotonin 5-HT₄ receptor binding in guinea pig striatum utilizing [3H]-GR113,808 was performed by MDS Pharma Services [formerly Panlabs Taiwan] according to the method of Grossman and Kilpatrick.⁵⁷

**Selectivity Binding Assays**

The following radioligands were used for receptor profiling studies: [3H]-5HT for 5-HT₁-like receptors; [3H]-ketanserin for 5-HT₂ receptors; [3H]-SCH23390 for D₁ receptors; [3H]-spiperone for D₂ receptors; and [3H]-prazosin for α₁-adrenergic receptors.

**In Vitro Functional Assay for Serotonin 5-HT₄ agonism in the Rat TMM (tunica muscularis mucosae) Assay**

Serotonin 5-HT₄ agonism was measured in the rat esophagus in vitro preparation as reported by Baxter.²,⁵⁷ Agonist activity was determined utilizing relaxation of carbachol-contracted rat tunica muscularis mucosae. One 2 cm segment of intrathoracic esophagus proximal to the diaphragm was removed from male rats weighing approximately 300 g, and the outer muscle layers removed. The inner tunica muscularis mucosa was mounted under 0.2-0.3 g of tension in a tissue bath containing oxygenated Tyrode's solution at 37°C. Cortisosterone acetate (30 µM) and fluoxetine (1 µM) were included in the buffer to
prevent uptake of serotonin, as well as pargyline (10 µM) to inhibit monoamine oxidase.

Following a 30 min equilibrium period, tissues were isometrically contracted with
carbachol (3 µM) to obtain a tonic contraction. A stable plateau was obtained within 20
min when test compound was added cumulatively to relax the muscle strip. EC50 values
were obtained for each agonist in tissues from rats.

5-HT4 Receptor Antagonism in the Rat TMM (tunica muscularis mucosae) Assay

Antagonist activity of compounds at 5-HT4 receptors was determined in a manner
similar to the in vitro agonism activity described by Gullikson.39 Cumulative dose-
response curves for agonists interacting with 5-HT4 receptors of rat TMM were done
according to the method of Baxter.2 Male Sprague-Dawley rats (300 - 400 g) from
Charles River Laboratories (Wilmington, MA) were asphyxiated with CO2 and the TMM
were isolated from 2 cm segments of rat esophagus obtained orad to the diaphragm. the
TMM was mounted in a 37°C tissue bath under 2 to 3 mN of tension for 60 min before
the study. The tissues were suspended in and washed with continuously oxygenated (95%
O2/5% CO2) Tyrode's buffer which contained fluoxetine (1 µM) and corticosterone (30
µM) to prevent tissue uptake of 5-HT, methysergide (1 µM) to block 5-HT1 and 5-HT2
receptors, and pargyline (100 µM) to prevent oxidation of 5-HT by monoamine oxidase.
Selected concentrations of antagonist were added to the tissue bath 5 min after TMM
were contracted with 3 µM of carbachol. Relaxant responses to cumulative additions of 5-
HT or 5-HT4 agonists (from 10^-10 to 10^-5 M in half-log increments at 2.5-min intervals)
were started 20 min after addition of the carbachol. Agonist ability to relax TMM was
expressed relative to the maximum relaxant response by the agonist in the absence of
antagonist. EC\textsubscript{50} values were calculated as the concentrations causing 50% of this maximal effect. EC\textsubscript{50} ratios (dose ratios) from the agonist concentration-response curves in the absence and presence of three increasing concentrations of antagonist for each tissue were calculated. Dose ratios from at least four tissues for each of the three antagonist concentrations were used for Schild plot analysis to determine the mean pA\textsubscript{2} value ± S.E.M. of the antagonist.\textsuperscript{58} The pA\textsubscript{2} value for single antagonist concentrations in individual tissues was also calculated using the method of MacKay: pA\textsubscript{2} = -log (antagonist concentration [mol/l]) + log (DR-1). A mean pA\textsubscript{2} value ± S.E.M. was calculated from the individual pA\textsubscript{2} values from at least four tissues for a single concentration of the antagonist.

**von Bezold-Jarisch Reflex Assay**

According to the method of Saxena and Lawang,\textsuperscript{40} the test sample was administered i.p. (mg/kg) to a group of 3 mice. Thirty minutes later, a 5-HT (0.25 mg/kg i.v.)-induced bradycardia was recorded in pentobarbital anesthetized animals. A greater than 50 percent (>50) reduction in the bradycardic response relative to vehicle-treated control mice is considered significant.

**Antral Motility in Conscious Fasted Dogs**

Gastric antral contractile activity is stimulated by prokinetic drugs which enhance gastric emptying of solid food.\textsuperscript{59} This contractile activity is thought to enhance gastric emptying by more rapidly reducing food particle size for passage through the pylorus. The ability of the test compound to increase the frequency and/or amplitude of the contractile activity is therefore a measure of GI prokinetic activity of compounds.
Mongrel dogs of either sex weighing 15-25 kg were surgically implanted with strain
gauge force transducers on the gastric antrum at 6 cm, 4 cm and 2 cm from the
gastroduodenal junction. Strain gauge transducers were also implanted on the ileum and
proximal colon. Silver monopolar electrodes were implanted on the jejunum. The dogs
were allowed at least two weeks to recover and were trained to stand quietly in Pavlov
slings. Dogs were fasted for 18-24 hours prior to each experiment to record a pattern of
antral contractile activity characteristic of the fasted state called the migrating motor
complex (MMC). The period of the MMC cycle is approximately 90-120 minutes and
consists of 45-60 minutes of motor quiescence (Phase I) 30-45 minutes of intermittent
activity (Phase II) and 10-15 minutes of intense contractile activity (Phase III). A control
MMC period is recorded prior to compound administration to obtain the length of the
quiescent Phase I period. Compound is given intravenously at the end of Phase III of the
control MMC cycle and the subsequent Phase I period is examined for the ability of the
compound to produce contractions. A compound is considered active if it produces any
contractile activity during the normally quiescent Phase I. A motility index of cumulative
activity consisting of frequency and amplitude components, is used to quantitatively
describe the total contractile activity of a time period after compound administration
equal to the control MMC period.

**Canine Gastric Emptying In Vivo Model**

Determination of the effects of test compounds on gastric emptying of solid meals in
nonsedated dogs was done in separate experiments in an α2-adrenergic model of
gastroparesis as described by Gullikson. Dogs weighing 15-25 kg were trained to
stand quietly in Pavlov slings for 3-4 hours, and consistent control emptying responses
were obtained prior to use in gastric emptying experiments with the test compounds. The solid meal consisted of 2 cooked scrambled eggs which were divided into 1 cm sized pieces and mixed with beef stew. One mCi of Tc-99m sulfur colloid was incorporated into the eggs prior to cooking. The dogs were fasted for at least 24 hours prior to the study and were fed the solid meal by intragastric tube. To delay normal gastric emptying 0.030 mg/kg of \( \alpha_2 \)-adrenergic agonist 2-methyl-3-[(2E)-pyrrolidin-2-ylideneamino]phenol was administered immediately following the meal. The test compounds were given via intravenous injection 45 minutes prior to feeding.

A Siemens 370 ZLC gamma camera with high resolution low energy collimator was used to acquire left lateral images during emptying studies. Acquisition times were 3 min/frame for 180 min solid emptying. Disappearance of contents from the stomach region of interest was plotted over time to obtain emptying curves. The amount of solid meal remaining in the stomach at the end of each experiment and the fractional solid emptying rate (% emptied per min) were calculated from linear regression equations describing solid emptying. Emptying measurements obtained from one replicate of each drug treatment were compared to the means of at least 3 control responses for the \( \alpha_2 \)-adrenergic agonist in solid emptying studies.

**Ames Mutagenicity Assay**

Pyrrolizidine benzamide 12a was tested for mutagenic activity in a GLP study using the Ames Salmonella/microsome assay with five strains of Salmonella typhimurium (TA1535, TA100, TA1538, TA97, and TA98) in the presence and absence of a rat liver homogenate metabolic activation system (S9) over test article concentrations ranging
from 7.2 to 3600 µg/plate. Significant test article-related increases of 4X in the number of revertant colonies were observed in strain TA98 with activation at 3600 µg/plate. A 2-3X increase was observed with activation in strain TA100 between 710 µg and 3600 µg/plate, and a 2-6X increase was observed with activation in strain TA1538 also between 720 µg and 3600 µg/plate. Significant increases in numbers of revertant colonies were not observed in the test without S9 activation.

Pyrrolizidine benzamide ent-12a was tested for mutagenic activity in a GLP study using the Ames Salmonella/microsome assay with five strains of Salmonella typhimurium (TA1535, TA100, TA1538, TA97, and TA98) in the presence and absence of a rat liver homogenate metabolic activation system (S9) over test article concentrations ranging from 10 to 5000 µg/plate. There were no test article-related increases in the number of revertant colonies or cytotoxic effects observed in any of the tester strains with or without activation. These data support the conclusion that ent-12a is not mutagenic under the conditions of this test system.
