Toward True Integration of Academic and Behavior Response to Intervention Systems Part Three: Tier 3 Support

By Kent McIntosh, Hank Bohanon, & Steve Goodman

In articles one and two in this series, we described strategies for integrating academic and behavior response to intervention (RTI) systems at Tiers 1 and 2 (McIntosh, Bohanan, & Bohanan, 2010; McIntosh, Bohanan, & Goodman, 2010). This article will illustrate how integrated academic and behavior RTI systems can work at Tier 3. When students are not successful with academic or behavior support at Tiers 1 and 2, more resources need to be dedicated to support them. These resources include the time required in increasing support and the technical skills required for intervening and monitoring progress. Because ameliorating intensive student challenges requires school personnel with the most highly specialized skills, school districts often rely on the same integrated support teams for both tiers than create specific Tier 3 teams. If the presenting problem is in one area only, there is a strong likelihood that intensive intervention creates barriers, especially when problems spill over into other areas when the level of student need intensifies. Students at Tier 3 require intensive instruction, and integrated support may help provide students with more opportunities for practice and success across both domains. Consequently, integrating these systems can make support both more comprehensive and more streamlined.

Integrating Tier 3 Support

When progress monitoring data show an inadequate response to the efficient support provided in Tier 2, more intensive and individualized support is indicated. However, the same teaming and decision-making structures used in Tier 2 still apply at Tier 3 (McIntosh, Bohanan, & Goodman, 2010). Because teaming at Tier 3 involves the same activities of screening, assessment, intervention, and progress monitoring, it makes more sense to rely on the same integrated support teams for both tiers than create specific Tier 3 teams. At times, the school team may need to invite additional members (e.g., family members, mental health experts, community agency representatives) to create student-specific wrap-around teams (Eber et al., 2009), but the integrated support team can still coordinate and monitor the effectiveness of support. The characteristic distinction between Tiers 2 and 3 is the intensification and individualization of support that occurs at Tier 3. This difference can be seen most clearly in the processes of assessment and intervention.

Assessment

Though Tier 2 assessment may focus on efficiency of assessment to conserve resources for intervention (Vaughn & Fletcher, 2010), Tier 3 support can be hindered by too little attention to assessment. One of the clear benefits of an RTI system is the rich amount of data collected before Tier 3 support begins. Integrated support teams can review previously collected Tier 2 progress monitoring data and identify what additional information is needed to plan effective support. It is useful to assess functioning in three domains: academic performance, behavior needs, and quality of life. Though it may seem unnecessary to assess needs in each domain if the presenting problem is in one area only, there is a strong likelihood that intensive problems in one area will lead to problems in the others (McIntosh, Horner, Chard, Boland, & Good, 2006; Reinke, Herman, Petros, & Ialongo, 2008). In these situations, it can be helpful to identify whether academic skills deficits evoke problem behavior to escape tasks or attention-maintained problem behavior is disrupting academic instruction, as each circumstance has different implications for intervention. Moreover, students with challenges in academics or behavior are at risk for diminished quality of life because behavior challenges restrict access to positive social outcomes, and academic challenges intervention creates barriers, especially when problems spill over into other areas when the level of student need intensifies. Students at Tier 3 require intensive instruction, and integrated support may help provide students with more opportunities for practice and success across both domains. Consequently, integrating these systems can make support both more comprehensive and more streamlined.

Hypothesis Statement

A hypothesis statement is adapted from material originally published by the RTI Action Network (http://www.rtinetwork.org/learn/behavior), copyright 2009 by National Center for Learning Disabilities, Inc. Used with permission.

At Tier 3, bringing in family members can enhance the selection of targets for intervention, encourage effective problem solving, and build an alliance that can extend support across settings (Eisler, Godder, & Christenson, 2008). If a child has limited support outside of the school environment, there may be barriers in access to academic support at home and consistency in monitoring and acknowledging prosocial behavior throughout the day. As a result, school personnel and families alike can experience frustration with the assessment process. Therefore, assessment in all of the systems of an individual’s life (e.g., school, home, peers, community) can be beneficial in improving outcomes (Hengge, Schoenwald, Bordin, Rowland, & Cunningham, 2009).

The functional behavior assessment—behavior support planning (FBA–BSP) process is a helpful framework for organizing integrated Tier 3 assessment and intervention. Though it is more commonly associated with behavior support for students with significant needs (O’Neill et al., 1997), Tier 3 academic and integrated interventions can also be generated from this logic of comprehensive skill-based and academic and environmental support (Witt, Daly, & Noell, 2000). Moreover, there is ample evidence of its effectiveness in general education settings (McIntosh, Brown, & Borgmeier, 2008). Through the FBA–BSP process, teams identify a hypothesis statement, including (a) a clear definition of the behavior of concern, (b) the immediate antecedents, (c) the setting events, and (d) the maintaining consequences. Quality of life assessment, in the areas of emotional, environmental, and social well-being (Poston et al., 2003) can then be used to identify potential alternative behaviors and long term objectives. Additional Tier 3 assessment can involve diagnostic assessment, including brief experimental analysis (Daly, Andersen, Gortmaker, & Turner, 2006) and can’t do/won’t do assessment (VanDerHeyden & Witt, 2008).

Intervention

Though it may be more efficient to provide separate academic and behavior interventions at Tier 2 (McIntosh, Bohanan, & Goodman, 2010), integrated support is necessary for enhanced outcomes at Tier 3. A key feature of Tier 3 support is the focus on individualized intervention matched to student need. Consideration of both academic and behavior difficulties allows for a more comprehensive individualized intervention. In the FBA–BSP process, the hypothesis statement is used to identify strategies that will make problems (or academic errors) unlikely, inefficient, and ineffective (Suga, Lewis-Palmer, & Hagan, 1998). Specific strategies are generated and selected based on their potential effectiveness and fit with the skills, resources, and values of the implementers and stakeholders (Albin, Lucynshyn, Horner, & Flannery, 1996). Strategies are organized by (a) behavior strategies, (b) antecedent strategies, (c) setting event strategies, and (d) consequence strategies. The result is a comprehensive plan integrating academic, behavioral, and quality of life interventions.

Behavior Strategies

Academic and behavior interventions both focus on teaching as the most important intervention in education. Academic interventions involve teaching important skills that are missing or deficient. Behavior interventions also involve missing or deficient skills, though with a focus on teaching missing or underused prosocial skills.

For remediation of any skill (academic or behavior), interventions must include high quality instruction. High quality instruction (a) focuses on critical, functional skills, (b) uses explicit teaching, (c) is carefully sequenced, (d) emphasizes the use of conspicuous consequences, (e) uses scaffolding to promote student success, (f) utilizes prior knowledge, and (g) provides regular opportunities for practice (Coyne, Kame’enui, & Carnette, 2007). Intervention strategies may involve a range of instructional methods.

When academic skills change, it is important to identify the right specific skill to target. The instructional hierarchy (acquisition, fluency, generalization, and adaptation; Haring, Lovitt, Eaton, & Hansen, 1978), in combination with validated models of academic development, can inform the identification of target skills. For example, low accuracy indicates the need to focus on acquisition, with performance feed-
back as a critical component, whereas high accuracy but low rates of responding indicate difficulty as a goal, with extensive practice as important (Daly, Lentz, & Boyer, 1996).

When problem behavior is the target for change, the instructional hierarchy can also be used, but the primary focus is on teaching functionally equivalent alternative behaviors, behaviors that serve the same function as problem behavior but are more socially appropriate (O’Neill et al., 1997). For instance, students can learn to request assistance or escape from a frustrating activity. Students can also be taught to solicit peer or adult attention appropriately or self-monitor their progress and initiate problem solving as needed.

Set antecedent strategies. Antecedent strategies involve changing the environment to make desired skills less difficult to perform. For example, the difficulty of tasks can be reduced to match the student’s instructional level (Lee, Sugai, & Horner, 1999). Common strategies include providing a distraction-free work environment and scaffolding, through the use of advanced organizers, or assistance from adults or peers. When academic task demands are the antecedents to problem behavior, these academic skills can be pretaught to make the task easier to perform, thereby preventing the need for problem behavior. In addition, before situations where challenges are likely, students can be reminded to use alternative behaviors instead of problem behaviors (Colvin, Sugai, Good, & Lee, 1997).

Setting event strategies. Setting event strategies involve preventing or neutralizing environmental conditions that inhibit desired performance (Horner, Vaughn, Day, & Ard, 1996). These strategies can be considered as steps to reduce distractions and enhance the environment to optimize student learning and performance, often in the form of addressing quality of life needs identified through the assessment process (Eber et al., 2009; Kincaid, 1996). Though setting events can occur during school hours, school challenges can also be intensified by challenges outside of school that affect academic or behavior performance (e.g., sleeping in class because there is no bed at home; Edmondson & Turnbull, 2002). In these circumstances, the home environment can be targeted as part of a comprehensive plan to help enhance school performance (e.g., helping the student get to school on time, providing a quiet space and performance feedback for homework completion; Esler et al., 2008). In other circumstances, problems in or out of school cannot be prevented, but neutralizing routines can be used to minimize their effects (Horner, Day, & Day, 1997). For example, engaging students in positive or neutral interactions that are not related to academic or behavior problems may reduce feelings of isolation and enhance school engagement.

Consequence strategies. Consequence strategies involve ensuring that the desired behaviors are reinforced and problem behaviors are not inadvertently reinforced. One of the critical aspects of these strategies is to help students make the connection between desired behaviors and natural reinforcement. For instance, completing activities to improve reading fluency should help students read materials in their interest areas more easily. Behavior interventions should be designed to lead to enhanced capacity to build and maintain positive social interactions or cope more effectively with difficult situations. However, before students can access natural reinforcement for using skills, structured reinforcement systems can be effective to acknowledge small successes and encourage use and practice until they can use them independently (Akin-Little, Eckert, Lovett, & Little, 2004). In the case of problem behavior, it is important to ensure that the alternative behavior is functional—that it provides access to preferred interactions, activities or objects, or escape from aversive situations (O’Neill et al., 1997).

Holding the student so that it is important to ensure that problem behavior is not inadvertently reinforced. For example, work refusal can be reinforced by removing the request. Instead, school personnel can encourage the student to ask for a break, upon which a brief break from the task can be provided, and the task can be reattempted when the student is ready. Adding punishment procedures should only be considered once all other components of a plan are in place. As long as problem behavior is not reinforced, punishment may not be needed for plans to be effective.

Case study example

To illustrate how the FBA–BSP process can be used for integrated Tier 3 academic and behavior support systems, we provide an example of a fictitious Grade 6 student named Keenan. After his needs were identified through universal screening, Keenan was provided Tier 2 academic support targeting his reading fluency and additional scaffolding in the form of graphic organizers. The team also identified an alternative behavior to replace work refusal. Keenan was taught that when he felt frustrated, he could request to read preferred reading materials and use positive self-talk to counter negative thoughts. Consequence strategies were also selected to ensure that the alternative behavior could be used more frequently. When frustrated, and would work during independent work time, reading either the assigned work or back as a critical component, whereas high accuracy but low rates of responding indicate difficult behavior. (pp. 439–463). Baltimore: Brookes.}
