A NOVEL SYNTHETIC ROUTE TO 5-SUBSTITUTED INDOLES

A THESIS SUBMITTED TO
THE FACULTY OF THE GRADUATE SCHOOL
IN CANDIDACY FOR THE DEGREE OF
MASTER OF SCIENCE

DEPARTMENT OF CHEMISTRY

BY
HELEN Y. CHEN

CHICAGO, ILLINOIS
JANUARY 1998
The author wishes to thank Dr. James Babler for the opportunity to study under his guidance for a Master of Science degree.

In addition, the author would like to thank many of the staff at G.D. Searle for their generous support, allowing the author to perform much of the research at their laboratories--most notably Alan Moorman for his excellent mentorship and helpful discussions.

Thanks also to Dr. Frank DiNinno of Merck & Co. for his assistance in the interpretation of some spectra.

Special thanks to my husband, Ezra, for his patience and support as I devoted my time to courses and the writing of the thesis.

And most of all, thanks be to God who oversaw everything and in His perfect timing, enabled me to complete the Master's program.

The indole skeleton, shown above, is one of the most widely distributed heterocyclic systems in nature. This ring system is not only present in dyes and alkaloids, but can also be found in the plant growth-regulating hormone indol-3-ylacetic acid, the essential amino acid tryptophan, and tryptamine. It is a building block for preparing a number of biologically active compounds including Indomethacin, one of the major treatments for rheumatoid arthritis, and several central nervous system depressants.

Substituted indoles are versatile intermediates in the synthesis of compounds possessing biological activity. For example, 5-substituted indoles have found their utility as starting materials in multi-step syntheses of several pharmaceutical drug targets. For instance, 5-bromoindole has been
used in the synthesis of selective serotonin (5-hydroxytryptamine) antagonists of the general formula 1 for the treatment of disorders of the central nervous system. In the synthesis of peptidoleukotriene antagonists for the treatment of asthma, 5-nitroindole was alkylated to give, after a multi-step sequence of reactions, compounds with the general formula 2.

Due to their significance to biological systems, the indole nucleus has been a target and problem in organic synthesis for almost a century. Perhaps the most widely explored and used route for the synthesis of indoles is the classical Fischer synthesis. In its simplest form, the Fischer indole synthesis, first discovered in 1883, involves the acid-catalyzed rearrangement of an arylhydrazone, such as 3, with the liberation of ammonia.

Although the Fischer synthesis is quite general, it is not applicable for the preparation of 2,3-unsubstituted indoles. In addition, for substitution in the 4, 5, 6, or 7 positions of the indole nucleus, the method requires the appropriately substituted arylhydrazones which are often not readily available.
Therefore, an efficient conversion of commercially available anilines to indoles would be a useful synthetic goal. Several routes in the past have been developed to accomplish this. The Gassman indole synthesis involves a one pot reaction in which hypohalite and base are added sequentially to an aniline to produce 3-thioalkoxyindoles. Raney-nickel reduction then yields the desulfurized indole.

![Chemical Reaction Diagram]

The Gassman synthesis has good generality not only for 2-substituted indoles, but also for 2,3-unsubstituted indoles. One major drawback of this route, however, is its ineffectiveness in preparing indoles such as 5-methoxyindole and 7-methoxyindole. Both the Fischer and the Gassman methods require a sigmatropic rearrangement to effect the crucial ortho substitution.

Other syntheses that convert anilines to indoles depend on having the appropriate ortho substituent built into the reactant. Although these routes tend to be regioselective, like the Fischer indole synthesis, the availability of starting materials is again a cause for concern. Some of these syntheses include cyclization of 2-vinyl-N-tosylanilines in the presence of a Pd(II) catalyst, palladium-catalyzed cyclization of o-alkynylanilines, generation of ortho-(2-oxoalkyl)anilines from a SRN1 reaction of o-iodoaniline followed by intramolecular cyclization, reductive cyclization of o-
chloroacetylated anilines (7) and cyclization via an intramolecular Heck reaction on compound 8.

![Chemical structures](attachment:ChemicalStructures.png)

Another conceptually attractive approach to indoles from anilines involves cyclization of α-anilino acetals (9) via an acid-catalyzed intramolecular electrophilic aromatic substitution. α-Anilino acetals can be obtained simply by treating the corresponding aniline with acetal derivatives of an α-haloaldehyde.

\[
\begin{align*}
&\text{XCH}_2\text{CHYZ} \\
&\text{where } X=\text{Cl}, \text{Br} \\
&Y, Z=\text{OR}'
\end{align*}
\]

Initially, only limited success was obtained by Forbes and co-workers, who observed that cyclizations only occurred for N-alkylated acetals 10.\(^{11}\)

![Chemical structure](attachment:ChemicalStructure10.png)

\[
\text{EtO}_2\text{N} \xrightarrow{\text{BF}_3\text{AcOH}, (CF_3CO)_2\text{O}, 5^\circ \text{C}} \xrightarrow{60\% \text{ yield}} \text{R=Me, Et}
\]
In general, good yields (60% and above) were obtained for 4-methoxy-N-methylindole and 6-methoxy-N-methylindole. As Sundberg and co-workers pointed out\textsuperscript{12}, the failed cyclization of N-unsubstituted indoles could be attributed to two potential problems associated with this approach. First, protonation or coordination at the free nitrogen would disfavor cyclization by retarding the desired electrophilic substitution. Secondly, N-unsubstituted indoles are unstable to protic and Lewis acid conditions so that subsequent reaction of the initial product could occur. In another instance, Jackson and co-workers\textsuperscript{13} observed a considerable amount of polymerization after attempting cyclization of an N-unsubstituted system, $m$-methoxyanilinoacetaldehyde diethyl acetal, with dilute HCl in dioxane.

Not until recently did several groups, including Sundberg’s and Nordlander’s, demonstrate the feasibility of this approach for N-unsubstituted indoles. Nordlander\textsuperscript{14} addressed the potential problems discussed above by developing the following scheme:

\begin{equation*}
\begin{array}{c}
\text{EtO} \quad \text{EtO} \\
\text{R} \quad \text{EtO} \\
\text{N} \quad \text{EtO} \\
\end{array}
\xrightarrow{(\text{CF}_3\text{CO})_2\text{O}}
\begin{array}{c}
\text{EtO} \quad \text{EtO} \\
\text{R} \quad \text{EtO} \\
\text{N} \quad \text{EtO} \\
\end{array}
\xrightarrow{(\text{CF}_3\text{CO})_2\text{O}}
\begin{array}{c}
\text{R} \quad \text{CF}_3\text{COF} \\
\text{N} \quad \text{CF}_3\text{COF} \\
\end{array}
\xrightarrow{0^\circ\text{C to reflux}}
\begin{array}{c}
\text{R} \quad \text{CF}_3\text{COF} \\
\text{N} \quad \text{CF}_3\text{COF} \\
\end{array}
\xrightarrow{\text{KOH}}
\begin{array}{c}
\text{R} \quad \text{COCF}_3 \\
\text{N} \quad \text{COCF}_3 \\
\end{array}
\end{equation*}

 Appropriately substituted N-(trifluoroacetyl)-$\alpha$-anilino acetals (11) produced N-(trifluoroacetyl)indoles (12) in high yields simply by refluxing with
trifluoroacetic acid and excess trifluoroacetic anhydride. By first incorporating
the trifluoroacetyl group before cyclization, the basicity of the aniline nitrogen
was decreased and the final product indole was stabilized. In addition, N-unsubstituted indoles could readily be obtained in quantitative yields by
saponification of the initially-formed amide \((\text{12})\) with potassium hydroxide.
For example, 5-methylindole was produced in 86% yield after 72 hours of
heating. Unfortunately, the process failed for generating 7-substituted
indoles and for substrates with electron withdrawing groups on the benzene
ring (i.e. Br).

A few years later, Sundberg and co-workers\(^{12}\) showed that the
methanesulfonamide derivatives of N-(2,2-diethoxyethyl)anilines \((\text{13})\) could
also be cyclized to indoles in aromatic solvents by treatment with titanium
tetrachloride.

Like the trifluoroacetyl group, the methanesulfonyl group could then be
removed simply by basic hydrolysis conditions. The temperature at which
cyclization proceeded relied heavily on the nature of the substituents on the
ring. For substrates with strongly activating groups, reaction occurred at 0°C;
whereas, rings containing mildly deactivating substituents required heating to
110-130°C. Specifically, 5-methylindole was produced in 83% yield after
heating at 110°C for 15-30 minutes. Interestingly, Sundberg also noted the
failure of this approach towards the preparation of 7-substituted indoles.
The general concept of this method has recently been applied to the synthesis of several natural products for which other cyclization conditions have also been developed. For example, Cherif and colleagues\textsuperscript{15} have shown that 4,7-dimethoxyindoles could be synthesized in 63% yield via cyclization of N-(trifluoroacetyl)-\(\alpha\)-(2,5-dimethoxyanilino)acetaldehyde diethyl acetal (14) in refluxing xylene and PPA. Researchers at Banyu Pharmaceutical\textsuperscript{16} have also successfully used this method in their total synthesis of a new topoisomerase II inhibitor BE 10988. Cyclization on the N-alkylated amine 15 proceeded in 42% yield upon treatment with ZnCl\textsubscript{2} in DMF.

![Chemical structures](image)

In conclusion, cyclization of acetal derivatives of \(\alpha\)-anilino acetaldehydes has been demonstrated to be a viable synthetic route to indoles, especially 5-substituted indoles, for which the regioselectivity is fixed. Sundberg writes, "In terms of being a practical indole synthesis, this route appears to compare favorably with other methods which start from substituted anilines and is particularly suitable for 5-substituted indoles with electron-donor substituents."\textsuperscript{12}
CHAPTER II
STATEMENT OF PROBLEM

Although the existing literature has demonstrated the feasibility of this route for the synthesis of 5-substituted indoles with cyclizations proceeding in 60-86% yields, the formation of the key synthetic intermediate, an acetal derivative of α-anilino acetaldehyde (I), by the conventional alkylation of aniline with α-haloacetaldehyde acetals requires high temperatures and extended reaction times. A typical procedure includes refluxing the appropriately substituted aniline (1.5 eq.) in DMF or EtOH with an acetal derivative of bromoacetaldehyde (1.0 eq.) and NaHCO₃ (1.5 eq.) for >48 h to 96 h.¹⁴,¹⁵ A specific example for p-toluidine is given below.

Yields generally range from 54-71% depending on the electronic nature of the substituents. However, in cases where coupling was performed using N-alkylated anilines with several substituents on the benzene ring, yields appeared to be lower (26-32% yield).¹⁶,¹⁷ Few attempts have been made to improve this route. Sundberg and his co-workers briefly examined the use of 2-(bromomethyl)-1,3-dioxolane in place of the bromoacetaldehyde diethyl acetal.
in his alkylation of N-methanesulfonyl anilines. He was able to reduce the reaction time from 48-60 h to <20 h.\textsuperscript{12}

We propose an alternative route to 5-substituted indoles using 2-chloro-1,1,2-tributoxyethane (16), a much more reactive alkylating reagent than bromoacetaldehyde diethyl acetal, to alkylate the aniline. 2-Chloro-1,1,2-tributoxyethane can be readily prepared from inexpensive glyoxal in two steps. Subsequent alkylation of the aniline with 16 affords an imine, which upon reduction produces essentially the same substrate 9 (differing only in the OR group of the acetal) necessary for the cyclization conditions developed by Nordlander.\textsuperscript{14}

\[
\begin{align*}
  \text{R-\text{NH}_2} + \text{Cl-\text{OBu-OBu}} & \rightarrow \text{R-\text{BuO-OBu}} \\
  \text{Reduction} & \rightarrow \text{R-\text{BuO-OBu}} \\
\end{align*}
\]

A similar alkylation has recently been demonstrated by J. Babler to occur in 82% yield when benzylamine is treated with $\alpha$-chloroether 16.\textsuperscript{18} Therefore this route would offer another option for converting substituted anilines to indoles.
CHAPTER III
RESULTS AND DISCUSSION

This thesis presents preliminary results obtained by applying the novel synthetic route outlined in Scheme I to the preparation of 5-methylindole. As the first test case of this methodology, p-toluidine was primarily chosen in view of its greater capability, relative to aniline, for nucleophilic attack on 2-chloro-1,1,2-tributoxyethane.

Scheme I

\[
\begin{align*}
\text{HCHO} &\xrightarrow{\text{n-BuOH (excess) cat. p-TsOH, toluene reflux, 3.5 h}} \text{BuO}^+\text{O}^-\text{Bu}^+\text{O}^-\text{Bu}^+ \\
\text{H}_3\text{C} &\text{NH}_2 \xrightarrow{16} \text{H}_3\text{C}^+\text{BuO}^+\text{O}^-\text{Bu}^+ \\
\text{H}_3\text{C} &\text{BuO}^+\text{O}^-\text{Bu}^+ \xrightarrow{\text{BH}_3}\text{pyridine} \xrightarrow{\text{CH}_2\text{Cl}_2 r.t., 2 h} \text{H}_3\text{C}^+\text{BuO}^+\text{O}^-\text{Bu}^+ \\
\text{H}_3\text{C} &\text{BuO}^+\text{O}^-\text{Bu}^+ \xrightarrow{\text{NEt}_3, \text{hexane (CF}_3\text{CO})_2\text{O} 0^\circ\text{C-r.t., 1.5 h}} \text{H}_3\text{C}^+\text{BuO}^+\text{O}^-\text{Bu}^+ \\
\text{H}_3\text{C}^+\text{BuO}^+\text{O}^-\text{Bu}^+ \xrightarrow{\text{KOH}} \text{H}_3\text{C}^+\text{BuO}^+\text{O}^-\text{Bu}^+ \\
\end{align*}
\]
p-Toluidine was N-alkylated using 2-chloro-1,1,2-tributoxyethane (16) under mildly basic conditions in CH$_3$CN and the resulting imine (18) subsequently reduced with BH$_3$•pyridine to give the key synthetic intermediate (19) in 30% overall yield over the two-step process. Subsequent treatment of 19 with trifluoroacetic anhydride gave the corresponding trifluoroacetamide derivative (20) in quantitative yield. Cyclization of 20 to generate 5-methylindole could then be achieved using literature procedures reported by Nordlander.$^{14}$

The alkylating agent, 2-chloro-1,1,2-tributoxyethane, was prepared using a modification of Babler's literature procedure.$^{18}$ Aqueous glyoxal was converted to the corresponding bis(dibutyl acetal) (17) by refluxing with excess 1-butanol and a catalytic amount of p-toluenesulfonic acid in toluene. Typical yields for acetal formation ranged from 74-85% yield. 2-Chloro-1,1,2-tributoxyethane was subsequently obtained in 78% yield by treating glyoxal bis(dibutyl acetal) with excess acetyl chloride.

Several reaction conditions were explored to optimize the key alkylation of p-toluidine with 2-chloro-1,1,2-tributoxyethane. These are given in Table I.

*Unidentified products or structures tentatively assigned by ¹H NMR; Further data (IR, MS, ¹³C NMR) necessary to unequivocally identify reaction products.
The reaction was critically dependent on solvent and temperature conditions. Most of the difficulties encountered were related to the reactivity of the alkylating agent 16 not only to the desired SN₂ reaction with p-toluidine, but also to the competing elimination reaction. In general, by increasing the polarity of the solvent and lowering the temperature, higher yields of the desired product could be obtained.

Initially, I examined reaction conditions (DMF, K₂CO₃, 0°C) reported by Babler²³ to give alkylation of benzylamine by α-chloroether 16 in 82% yield. However, in the case of p-toluidine, the same conditions afforded the desired imine 18 in just 31% chromatographed yield even after heating at 60°C for 3.5 h. The reaction appeared sluggish with more than 50% of the p-toluidine being recovered unreacted. Proton NMR analysis of the reaction product mixture also revealed the formation of a significant amount of an unidentified by-product. When the crude reaction mixture was directly reduced with NaBH₄ in EtOH to the corresponding amino acetal 19, a major contaminant isolated from the reaction appeared to be a 1:1 mixture of p-toluidine and compound 23 (tentatively assigned). Proton NMR (CDCl₃) analysis appeared to be consistent with the structure drawn with Hₐ appearing as a triplet at 4.53 ppm and Hₐ appearing as a doublet at 3.58 ppm. However, more data would be required to unequivocally identify the side product.

When the alkylation was carried out neat at elevated temperatures, as shown in reactions 2 and 3 in Table I, p-toluidine was completely consumed.
within 5-10 minutes as determined by TLC and a considerable amount of tar was observed. However, no desired product was isolated from either one of those reactions. Instead, the major fraction isolated from plate layer chromatography in reaction 2 contained two unidentified products. By proton NMR analysis, these two products appeared very symmetrical as evident by the convergence of the -OCH₂CH₂CH₃ multiplet, present in the starting material and in the desired product, to a single triplet. Similarly, the product isolated from reaction 3 (with addition of K₂CO₃) also suggested a symmetrical compound. One possible structure that might fit the available data is the fragmented piece shown below or some derivative/polymer of it:

```
H₃C
```

However, further characterization is necessary to unequivocally identify the structure.

In the more basic solvents such as NMP, pyridine, and 1,2-DME (reactions 4, 6, and 7 in Table I), decomposition of 2-chloro-1,1,2-tributoxyethane via competing elimination reactions appeared to be faster than reaction with p-toluidine. No desired products were isolated from these reactions. Similarly, in a relatively non-polar solvent such as dioxane (entry 5 in Table I), alkylation of p-toluidine failed. Instead generation of the hydrochloride salt of p-toluidine and hydrolysis of 2-chloro-1,1,2-tributoxyethane to an aldehyde-containing compound was detected in the crude proton NMR spectrum (CHO, 9.46 ppm).

After some exploration of alternative reaction conditions, satisfactory results were achieved by using CH₃CN as the solvent, as indicated in entry 8
in Table I. A typical procedure is as follows: 1.2 equivalents of p-toluidine was treated with 1.0 equivalent of 2-chloro-1,1,2-tributoxyethane and 1.3 equivalents of K$_2$CO$_3$ in CH$_3$CN at 0°C and subsequently stirred at room temperature for 2 hours. The reaction proceeded more cleanly and more efficiently in CH$_3$CN than in DMF as evident from the crude product's proton NMR spectrum. Also improving the yield were shortened reaction times and lower temperatures. Interestingly, a significant amount of white solid precipitated from the crude product after standing at room temperature or storage at 0°C for 24 h. Characterization of the precipitate by proton NMR analysis revealed it to be the p-toluidine hydrochloride. The remainder of the crude product, however, contained a 2:1 mixture of the desired imine and an unidentified side product also observed in the DMF reaction. Efforts to reduce the amount of this side product by maintaining the reaction temperature at 0°C overnight, proved fruitless. At 0°C, the reaction afforded mainly unreacted 2-chloro-1,1,2-tributoxyethane with trace amounts of the undesired side product.

Due to the sensitivity of imine 18 to chromatography on silica gel, reduction was performed on the crude product. Initial attempts to reduce imine 18 with NaBH$_4$ in EtOH failed, giving rise to incomplete reactions and recovery of the starting material. Even overnight stirring at room temperature did not effect the desired transformation. In contrast, treatment of imine 18 with BH$_3$•pyridine in methylene chloride accomplished the reduction within two hours at room temperature. β-amino acetal 19 was thus obtained in 30-36% chromatographed yields from the starting 2-chloro-1,1,2-
tributoxyethane. Its proton NMR spectrum compared favorably with literature references.\textsuperscript{19}

In summary, we have shown the aforementioned route to be a viable alternative synthesis to amide-acetal \textsuperscript{20} which can be readily cyclized to give 5-methylindole. Unlike the current conventional methods, alkylation of p-toluidine can be accomplished at room temperature within 3 hours using 2-chloro-1,1,2-tributoxyethane. In addition to offering a more reactive alkylating agent, this method also utilizes inexpensive and readily available starting materials. However, its one major drawback in comparison to other routes is the inferior yields obtained from the key alkylation of p-toluidine. This can be attributed to the instability of 2-chloro-1,1,2-tributoxyethane to the reaction conditions when the rate of nucleophilic attack is slow.

Further research would be required to provide cleaner and more efficient alkylation conditions. One possibility might be to generate a more nucleophilic aniline equivalent by an in situ generation of a negative charge on nitrogen. This could theoretically be accomplished by initially converting the substituted aniline to its N-trifluoroacetyl derivative, followed by abstraction of the NH proton by a base.

\[
\begin{align*}
\text{H}_3\text{C} & \quad \text{(CF}_3\text{CO})_2\text{O} & \quad \text{H}_3\text{C} & \quad \text{base} & \quad \left[ \text{H}_3\text{C} \quad \begin{array}{c}
\text{N} \\
\text{O} \\
\text{CF}_3
\end{array}\right] \\
\text{NH}_2 & \quad \text{Cl} & \quad \text{BuO} & \quad \text{Cl} & \quad \text{BuO}
\end{align*}
\]
A similar transformation has been done in the literature. Sundberg has successfully alkylated N-methylsulfonyl derivatives of anilines by initial treatment with NaH followed by addition of bromoacetaldehyde diethyl acetal. In this way, the yield of alkylation was increased from 66% yield after 96 hours in refluxing ethanol to 79% yield after 48-60 hours of heating in DMF at 110°C. In addition, further work would need to be directed at exploring the limits and application of this synthetic route to other substituted aniline systems.
CHAPTER IV
EXPERIMENTAL

General Methods. Proton NMR (\(^1\)H NMR) spectra were recorded on a GE-300 (300 MHz) instrument with Me\(_4\)Si as the internal standard and CDCl\(_3\) as the solvent. IR spectra were recorded using a Perkin-Elmer model No.1320 spectrophotometer. Elemental analyses and mass spectra were performed by the Physical Methodology Department, Searle Laboratories, G.D. Searle & Co.

Glyoxal Bis(Dibutyl Acetal) (17). A mixture of 40% wt. glyoxal (Aldrich, 4.193 g, 0.03 mol), 1-butanol (10.53 g, 0.14 mol), and p-toluenesulfonic acid (0.207 g, 0.97 mmol) in toluene (20 mL) was heated to reflux with continuous azeotropic removal of water (3.5 mL) for 3.5 h. The cooled reaction mixture was diluted with ether (20 mL) and washed with saturated aqueous NaHCO\(_3\) (2X40 mL) followed by brine (40 mL). The organic layer was collected, dried over Na\(_2\)SO\(_4\), and filtered. Concentration in vacuo gave the desired product as a pale yellow oil (7.3 g, 85% yield). 

\(^1\)H NMR (CDCl\(_3\)): \(\delta\) 0.92 (t, 12 H, \(J=7.5\) Hz, CH\(_3\)), 1.50 (sept., 8 H, \(\text{CH}_2\text{CH}_3\)), 1.58 (sept., 8 H, \(\text{CH}_2\text{CH}_2\text{CH}_3\)), 3.50-3.70 (m, 8 H, OCH\(_2\) ), 4.32 (s, 2 H, CH(OR)\(_2\)).\(^{13}\)C NMR (CDCl\(_3\), DEPT): \(\delta\) CH\(_3\) 14.28; CH\(_2\) 19.75, 32.41, 67.81; CH 102.95.

IR \(\nu_{\text{max}}\) (neat): 2860-2980 (C-H), 1080 (C-O) cm\(^{-1}\).
Anal. Calcd. for C\textsubscript{18}H\textsubscript{38}O\textsubscript{4}: C, 67.88; H, 12.03.

Found: C, 66.80; H, 12.15.

*The large discrepancy in the elemental analysis between the calculated carbon content and those experimentally found may be attributed to contamination of the sample with toluene. Trace amounts of toluene were also detected in the proton NMR spectra. Glyoxal Bis(Dibutyl Acetal) \textit{17} is a known compound reported in the literature (F. Chastrette et al., Synth. Commun., 1988, 18, 1343).

\textbf{2-Chloro-1,1,2-tributoxyethane (16)}. To a solution of \textit{17} (3.005 g, 11.4 mmol) in acetyl chloride (2.9 mL, 41 mmol) was added 1-butanol (0.42 mL, 4.6 mmol) under argon. After stirring at r.t. for 2 h, the reaction was concentrated in vacuo and the residue was azeotroped with toluene to remove low boiling impurities. The desired product was obtained as a pale yellow oil (2.071 g, 78% yield).

\textit{1H NMR (CDCl\textsubscript{3}):} \( \delta 0.92 \text{ (t, 9 H, } J=7.5 \text{ Hz, } \text{CH}_3 \), 1.40 \text{ (m, 6 H, } \text{CH}_2\text{CH}_3 \), 1.60 \text{ (m, 6 H, } \text{CH}_2\text{CH}_2\text{CH}_3 \), 3.50-4.00 \text{ (m, 6 H, } \text{OCH}_2 \text{ ), 4.54 \text{ (d, 1 H, } J=5.5 \text{ Hz, } \text{CH(OR)}_2 \text{), 5.43 \text{ (d, 1 H, } J=5.5 \text{ Hz, } \text{CHCl} \text{).}}

\textit{IR } v_{\text{max}} \text{ (neat):} 2880-2960 \text{ (C-H), 1080, 1110 } \text{ (C-O) cm}^{-1}.

Anal. Calcd. for C\textsubscript{14}H\textsubscript{29}O\textsubscript{3}Cl: C, 59.88; H, 10.41.

Found: C, 60.05; H, 10.64.

MS: 245 (M-Cl), 280.3 (M\textsuperscript{+}).

\textbf{4-Methyl N \textit{anilino}-2,2-dibutoxyethanimine (18)}. A mixture of \textit{16} (2.071 g, 7.4 mmol), \textit{p}-toluidine (Aldrich, 0.92 g, 8.6 mmol), and anhydrous K\textsubscript{2}CO\textsubscript{3} (1.296, 9.3 mmol) in CH\textsubscript{3}CN (HPLC-grade, 25 mL) was stirred under argon at 0°C for 1 h, then warmed to r.t. for 2 h. The reaction mixture was subsequently partitioned between water and ethyl acetate. The
organic layer was collected, washed with brine, and dried over MgSO₄. Concentration in vacuo gave an orange/yellow oil which darkened upon standing at room temperature. The oil was slurried with hexane and the undissolved white solid filtered off. The filtrate was reconcentrated in vacuo to give an orange/red oil (2.26 g, quantitative).

¹H NMR (CDCl₃): δ 0.92 (t, 6 H, J=7.5 Hz, CH₃), 1.40 (sept., 4 H, CH₂CH₃), 1.61 (sept., 4 H, CH₂CH₂CH₃), 2.36 (s, 3 H, ArCH₃), 3.55-4.00 (m, 4 H, OCH₂), 4.94 (d, 1 H, J=5.0 Hz, CH(OR)₂), 7.04 (d, 2 H, J=9.0 Hz, Ar), 7.17 (d, 2 H, J=9.0 Hz, Ar), 7.73 (d, 1 H, J=5.0 Hz, N=CH).

"Reduction of Imine 18." To a solution of 18 (2.26 g, 7.4 mmol) in CH₂Cl₂ was added BH₃-pyridine (Aldrich, 0.91 mL, 9.0 mmol) at 20°C under argon. After 2 h, the reaction was quenched with water and the resulting mixture extracted with ethyl acetate (2X). The combined organic layers were then washed with brine, and dried over MgSO₄. Concentration in vacuo afforded the desired product as an orange oil. The oil was purified by column chromatography (100 g Merck silica gel, mesh size 230-400) using 5% ethyl acetate/hexane as the eluent and the desired product (19) was isolated as a yellow oil (0.61 g, 30% yield).

¹H NMR (CDCl₃): δ 0.92 (t, 6 H, J=7.5 Hz, CH₃), 1.40 (sept., 4 H, CH₂CH₃), 1.58 (sept., 4 H, CH₂CH₂CH₃), 2.22 (s, 3 H, ArCH₃), 3.21 (d, 2 H, J=5.5 Hz, NHCH₂), 3.49 (m, 2 H, OCH₂), 3.65 (m, 2 H, OCH₂), 3.73 (b, 1 H, NH), 4.66 (t, 1 H, J=5.5 Hz, CH(OR)₂), 6.55 (d, 2 H, J=9.0 Hz, Ar), 6.99 (d, 2 H, J=9.0 Hz, Ar).

¹³C NMR (CDCl₃, DEPT): δ CH₃ 14.43, 20.91; CH₂ 19.92, 32.52, 47.14, 67.03; CH 101.65, 113.83, 130.26; C 127.35, 146.26.
Conversion of Amine 19 to the Corresponding Trifluoroacetamide Derivative (20). To a solution of 19 (0.307 g, 1.1 mmol) in hexane (3 mL) was added triethylamine (0.17 mL, 1.3 mmol) followed by trifluoroacetic anhydride (0.17 mL, 1.2 mmol) at 0°C under argon. The reaction was allowed to warm to room temperature and was subsequently stirred for 1.5 h. The reaction was then quenched with cold water and extracted with ether. The organic layer was collected, washed in succession with water and brine, and dried over MgSO₄. The solvent was removed in vacuo to give a yellow oil which darkened to red upon standing at room temperature. (0.41 g, 100% yield).

$^1$H NMR (CDCl₃): $\delta$ 0.83 (t, 6 H, $J=7.5$ Hz, CH₃), 1.29 (sept., 4 H, CH₂CH₃), 1.45 (sept., 4 H, CH₂CH₂CH₃), 2.30 (s, 3 H, ArCH₃), 3.48 (m, 2 H, OCH₂), 3.50 (m, 2 H, OCH₂), 3.73 (d, 2 H, $J=5.5$ Hz, NCH₂), 4.70 (t, 1 H, $J=5.5$ Hz, CH(OR)₂), 7.10 (s, 4 H, Ar).

$^{13}$C NMR (CDCl₃, DEPT): $\delta$ CH₃ 14.31, 21.58; CH₂ 19.77, 32.34, 54.26, 67.02; CH 99.40, 128.56, 130.19; C 115, 117, 137.65, 139.44.

IR $\nu$ max (neat): 2880-2960 (C-H); 1620, 1700 (C=O), 1510 (Ar), 830 (p-substitution, Ar) cm⁻¹.

Anal. Calcd. for C₁₉H₂₈N₂O₃F₃: C, 60.79; H, 7.52; N, 3.73.

Found: C, 60.84; H, 7.34; N, 3.74.
MS: 376 (M+H+).

**Literature Procedure**\(^4\) for Conversion of **11 to 12**
(Analogous for conversion of **19 to 21**). To 50 mL of 50% (v/v) \((\text{CF}_3\text{CO})_2\text{O}\) in \(\text{CF}_3\text{CO}_2\text{H}\) at 0°C under nitrogen was added 5.0 g (24 mmol) of **11**. After 30 min, the cold mixture was diluted with 40 mL of \(\text{CF}_3\text{CO}_2\text{H}\) and boiled under reflux for 72 h. Distillation gave 4.8 g (23 mmol, 95%) of **12**.

**Literature Procedure**\(^4\) for Hydrolysis of **12 to 5-Methylindole**
(Analogous for hydrolysis of **21**). Treatment of 3.0 g (14 mmol) of \(N\)-(trifluoroacetyl)indole (**12**) with 40 mL of 5% methanolic KOH at room temperature overnight, rotary evaporation of the bulk of the methanol, standard extractive workup with ether, and distillation (1 mm) gave 1.6 g (13.5 mmol, 86%) of 5-methylindole.

BIBLIOGRAPHY

VITA

Helen (Wu) Chen graduated as Valedictorian from Haddonfield Memorial High School, NJ in 1988. In 1992, she received her Bachelors of Art degree with magna cum laude in chemistry from Bryn Mawr College, PA. Soon after graduation, she joined the Process Research group of Bristol-Myers Squibb in Princeton, NJ where she worked on thrombin antagonists and β-lactams. After 2 years, she moved to Illinois and joined the medicinal chemists at G.D. Searle working on LTA$_4$ antagonists and in the area of anticancer agents. While at Searle, she resumed her education at Loyola University of Chicago, studying under the direction of Dr. James Babler for a Master of Science degree. In 1996, she moved back to NJ where she is currently employed at Merck & Co. as a medicinal chemist in the area of antibiotic research. She will receive her Master of Science degree in January 1998.
THESIS APPROVAL SHEET

The thesis submitted by Helen Y. Chen has been read and approved by the following committee:

James Babler, Ph.D., Director
Professor of Chemistry
Loyola University of Chicago

David Crumrine, Ph.D.
Professor of Chemistry
Loyola University of Chicago

Jonathan Zerkowski, Ph.D.
Assistant Professor of Chemistry
Loyola University of Chicago

The final copies have been examined by the director of the thesis and the signature which appears below verifies the fact that any necessary changes have been incorporated and that the thesis is now given final approval by the committee with reference to content and form.

The thesis is therefore accepted in partial fulfillment of the requirements for the degree of Master of Science.
